Injectable Bulking Agents for the Treatment of Urinary and Fecal Incontinence

**POLICY**

The use of carbon-coated spheres, calcium hydroxylapatite, or polydimethylsiloxane may be considered *medically necessary* to treat stress urinary incontinence in men and women who have failed appropriate conservative therapy.

The use of autologous cellular therapy (e.g., myoblasts, fibroblasts, muscle-derived stem cells, and adipose-derived stem cells), autologous fat, and autologous ear chondrocytes to treat stress urinary incontinence is considered *investigational*.

The use of any other peri-urethral bulking agent, including, but not limited to Teflon, to treat stress urinary incontinence is considered *investigational*.

The use of peri-urethral bulking agents to treat urge urinary incontinence is considered *investigational*.

The use of perianal bulking agents to treat fecal incontinence is considered *investigational*.

**POLICY GUIDELINES**

Patients should have had inadequate response to conservative therapy or therapies; in general, these treatments should have been used for at least 3 months. Conservative therapy for stress incontinence includes pelvic floor muscle exercises and behavioral changes, such as fluid management and moderation of physical activities that provoke incontinence. Additional options include intravaginal estrogen therapy, use of a pessary, and treatment of other underlying causes of incontinence in patients amenable to these treatments.

**CODING**

There are HCPCS codes for the bulking agents used in this procedure. L8603 describes collagen implant.
Injectable bulking agents for the Treatment of Urinary and Fecal Incontinence

material, such as Contigen (note: this product is longer commercially available), and L8606 describes synthetic bulking agents, such as carbon-coated beads or copolymers (Durasphere or Uryx). Physician services associated with urethral bulking agents are described by CPT code 51715. See coding section below.

There is also a HCPCS code for perianal bulking agent:

L8605: Injectable bulking agent, dextranomer/hyaluronic acid copolymer implant, anal canal, 1 ml, includes shipping and necessary supplies.

There is a CPT category III code specific to the Solesta procedure:

0377T: Anoscopy with directed submucosal injection of bulking agent for fecal incontinence.

BENEFIT APPLICATION

BLUECARD/NATIONAL ACCOUNT ISSUES

State or federal mandates (e.g., Federal Employee Program) may dictate that certain U.S. Food and Drug Administration–approved devices, drugs, or biologics may not be considered investigational, and thus these devices may be assessed only on the basis of their medical necessity.

Periurethral bulking agents may benefit both men and women with stress urinary incontinence. However, only Contigen®, which is no longer commercially available, has Food and Drug Administration approval for use in men and women.

BACKGROUND

Injectable bulking agents are space-filling substances used to increase tissue bulk. When used to treat stress urinary incontinence (SUI), bulking agents are injected peri-urethrally to increase tissue bulk and thereby increase resistance to the outflow of urine. The bulking agent is injected into the peri-urethral tissue as a liquid that solidifies into a spongy material to bulk the urethral wall. Bulking agents may be injected over a course of several treatments until the desired effect is achieved. Peri-urethral bulking agents have been widely used for incontinence in women. Men have also been treated, typically those with post-prostatectomy incontinence.

After the success of peri-urethral bulking agents for treating SUI, bulking agents injected into the anal canal have been proposed to treat fecal incontinence. In particular, bulking agents are a potential treatment for passive fecal incontinence associated with internal anal sphincter dysfunction. The bulking agent is injected into the submucosa of the anal canal to increase tissue bulk in the area, which narrows the opening of the anus. Current treatment options for fecal incontinence include conservative measures (e.g., dietary changes, pharmacotherapy, and pelvic floor muscle exercises), sacral nerve stimulation, and surgical interventions to correct an underlying problem.

Key factors in determining the optimal product are biocompatibility, durability, and absence of migration. A number of periurethral bulking agents to treat urinary incontinence have been cleared for marketing by the Food and Drug Administration (FDA); however, products developed to date have not necessarily met all criteria of the ideal bulking agents. The first FDA-approved product was cross-linked collagen (e.g., Contigen). The agent was found to be absorbed over time and symptoms could recur, requiring additional injections. Contigen production was discontinued in 2011. Other periurethral bulking agents cleared by FDA for urinary incontinence include carbon-coated beads (e.g., Durasphere), spherical particles of calcium hydroxyapatite (CaHA) in a gel carrier (Coaptite), polydimethylsiloxane (silicone, Macroplastique), and ethylene vinyl alcohol copolymer implants (e.g., Tegress, formerly Uryx). Tegress was voluntarily removed from the market due to safety concerns.
Several agents identical to or similar to those used for urinary incontinence (e.g., Durasphere, silicone biomaterial) have been studied for the treatment of fecal incontinence. To date, only 1 bulking agent has been approved by FDA for fecal incontinence. This formulation is a non-animal-stabilized hyaluronic acid/dextranomer in stabilized hyaluronic acid (NASHA Dx) and is marketed by Q-Med as Solesta. A hyaluronic acid/dextranomer formulation (Deflux™) from the same company has been commercially available for a number of years for the treatment of vesicoureteral reflux in children (see evidence review 7.01.102 on the treatment of vesicoureteral reflux with bulking agents).

Autologous fat and autologous ear chondrocytes have also been used as periurethral bulking agents; autologous substances do not require FDA approval. Polytetrafluoroethylene (Teflon) has been investigated as an implant material but does not have FDA approval. A more recently explored alternative is cellular therapy with myoblasts, fibroblasts, or stem cells (muscle-derived or adipose-derived). In addition to their use as periurethral bulking agents, it is hypothesized that transplanted stem cells would undergo self-renewal and multipotent differentiation, which could result in regeneration of the sphincter and its neural connections.

REGULATORY STATUS
Several periurethral bulking agents have been approved by FDA through the premarket approval process for the treatment of stress urinary incontinence due to intrinsic sphincter deficiency; other than Contigen®, approval is only for use in adult women. Products include:

- In 1993, Contigen® (Allergan), a cross-linked collagen, was approved. A supplemental approval in 2009 limited the device’s indication to treatment of urinary incontinence due to intrinsic sphincter deficiency in patients (men or women) who have shown no improvement in incontinence for at least 12 months. Allergan ceased production in 2011; no reason for discontinuation was provided publicly.
- In 1999, Durasphere® (Advanced UroScience), a pyrolytic carbon-coated zirconium oxide sphere, was approved.
- In 2004, Uryx® (CR Bard, Murray Hill, NJ), a vinyl alcohol copolymer implant, was approved. In 2005, approval was given to market the device under the name Tegress®. In 2007, Tegress® was voluntarily removed from the market due to safety concerns.
- In 2005, Coaptite® (Merz Aesthetics, previously BioForm Medical), spherical particles of calcium hydroxyapatite, suspended in a gel carrier, was approved.
- In 2006, Macroplastique® (Cogentix Medical, Minnetonka, MN), polydimethylsiloxane, was approved.

In 2011, NASHA Dx, marketed as Solesta® (Q-Med), was approved by FDA through the premarket approval process as a bulking agent to treat fecal incontinence in patients 18 years and older who have failed conservative therapy. FDA product code: LNM.

RATIONALE
The evidence review was created in December 1995 and has been updated regularly with searches of the MEDLINE database. This review was expanded to include fecal incontinence in 2013. The most recent literature update was performed through June 22, 2017.

Assessment of efficacy for therapeutic intervention involves a determination of whether the intervention improves health outcomes. The optimal study design for this purpose is a randomized controlled trial (RCT) that includes clinically relevant measures of health outcomes. Intermediate outcome measures, also known as surrogate outcome measures, may also be adequate if there is an established link between the intermediate outcome and true health outcomes. Nonrandomized
comparative studies and uncontrolled studies can sometimes provide useful information on health outcomes, but are prone to biases such as non-comparability of treatment groups, placebo effect, and variable natural history of the condition.

The literature on injectable bulking agents includes randomized controlled trials (RCTs) that compare bulking agents with alternative treatments or placebo. Therefore, this evidence review will focus on RCTs and systematic reviews of RCTs on use of injectable bulking agents to treat urinary and fecal incontinence. The following is a summary of key literature to date.

**URINARY INCONTINENCE**

A 2012 Cochrane review on periurethral bulking agents for urinary incontinence in women identified 14 RCTs (sample ranges, 30-355 patients) that included bulking agents in at least 1 of the study arms. This review updated a 2007 review. All trials included women with a urodynamic diagnosis of stress incontinence, and 7 trials limited eligibility to stress incontinence due to intrinsic sphincter deficiency. The trials varied by types of bulking agent and comparator interventions used. Eight studies compared 2 bulking agents, two compared bulking agents with surgery, one compared a bulking agent with pelvic floor exercise, and one used a placebo comparison group. Several studies required that women had experienced incontinence for a specified period of time (e.g., 6 or 12 months) and/or had already used conservative therapy; 1 study further specified that conservative therapy had to have been used for at least 3 months. Reviewers determined that the data were not suitable for pooling due to heterogeneity across trials. They concluded that there was insufficient evidence to guide practice and recommended that additional RCTs with a placebo group or conservative treatment arm be conducted.

A 2011 systematic review by Davila identified 20 studies meeting inclusion criteria (prospective clinical studies or RCTs conducted among women with stress urinary incontinence [SUI] and published in English). Nine studies (n=682 patients) evaluated the bulking agent cross-linked collagen. Rates of patients considered cured or improved in individual studies ranged from 21% to 81% at 12 months, 7% to 52% at 2 years, and 30% to 43% at more than 4 years. Eight trials (n=507 patients) used cross-linked polydimethylsiloxane injection. Cure rates ranged from 20% to 71% at 12 months and 18% to 40% at long-term follow-up (to 60 months). Reviewers concluded that bulking agents had demonstrated effectiveness at 1 year, but results, particularly with older agents, diminished over time, and required repeated injections to restore or enhance improvement.

**U.S. Food and Drug Administration–Approved Bulking Agents**

**Cross-Linked Collagen (Contigen)**

The 1996 clinical practice guidelines for urinary continence in adults concluded that periurethral collagen is curative in 32% of men and 62% of women. A 2005 RCT compared the efficacy of collagen injections with surgery in 133 women. Eligibility criteria included stress incontinence for at least 6 months or 1 year after delivery. Twelve-month success rates for collagen treatment (53%) were lower than for surgery (72%). However, there were significantly fewer adverse events in the collagen-treated group (36% vs 63%, respectively). No randomized trials comparing Contigen with conservative therapy or placebo were identified. Contigen is no longer commercially available.

**Carbon-Coated Beads (e.g., Durasphere)**

A 2001 double-blind, RCT comparing carbon-coated beads with cross-linked collagen was reported as part of the U.S. Food and Drug Administration (FDA)–approval process for Durasphere. The trial found no difference in efficacy or in number of treatments between groups, although trial duration (12 months) may not have been sufficient to assess comparative durability.
Injectable Bulking Agents for the Treatment of Urinary and Fecal Incontinence

**Ethylene Vinyl Alcohol Copolymer (eg, Tegress)**
The copolymer implant (Tegress; formerly Uryx) received FDA approval based on a trial that randomly assigned 237 women with SUI to undergo periurethral bulking with Uryx or to a “currently marketed absorbable bulking agent.” Efficacy at 12 months was similar between groups, with 18.4% of those receiving Uryx reporting that they were dry and 48.7% reporting improvement by 1 grade, compared with 16.5% and 53.2%, respectively, in the control group. A repeat injection was necessary in 75% of these patients to achieve satisfactory results. Following reports of adverse effects, Tegress was voluntarily withdrawn from the market by its manufacturer, CR Bard, in January 2007.

**Calcium Hydroxylapatite (eg, Coaptite)**
Calcium hydroxylapatite (Coaptite) received FDA approval based partly on results from a 2007 single-blind randomized non-inferiority comparison with collagen among women with SUI. This trial was later published and reported on 231 (78%) of 296 enrolled women. For the primary outcome measure, 83 (63%) patients treated with calcium hydroxylapatite and 57 (57%) control patients treated with collagen showed an improvement of 1 grade or more on the 4-grade Stamey Urinary Incontinence Scale at 12-month follow-up. Similar results were obtained by intention-to-treat analysis, with non-inferiority of calcium hydroxylapatite to collagen for improvement of at least 1 Stamey grade (58% vs 51%, respectively) and decrease in pad weight (51% vs 38%, respectively) of 50% or more.

**Polydimethylsiloxane (eg, Silicone, Macroplastique)**
FDA approval of polydimethylsiloxane (Macroplastique) was also partly based on a randomized non-inferiority comparison with collagen in women with SUI. The trial was single-blind; patients, but not providers, were blinded. At 12 months, Macroplastique was found to be non-inferior to collagen in terms of the primary efficacy variable, and improvement in the Stamey Urinary Incontinence Scale. Seventy-five (61%) of the 122 patients in the Macroplastique group and 60 (48%) of 125 patients in the collagen group improved at least 1 Stamey grade (p<0.001 for non-inferiority). Twelve of the 247 randomized patients were excluded from the analysis. Two-year data on 67 of the 75 women who responded to treatment with Macroplastique were published in 2010. Fifty-six (84%) of the 67 patients who had sustained treatment success at 24 months, defined as an improvement of at least 1 Stamey grade over baseline. Forty-five (67%) of the 67 patients evaluated at 24 months were dry (Stamey grade 0). The long-term analysis was limited because it only included a portion of responders from 1 arm of the trial. The analysis included 67 (55%) of 122 patients originally randomized to Macroplastique and did not provide data on the comparison group.

**Non-FDA-Approved Bulking Agents**

**Dextranomer/Hyaluronic Acid (eg, Zuidex) With an Injection System (eg, Implacer)**
Dextranomer/hyaluronic acid (Zuidex; AstraZeneca, Cambridge, England) with injection system (Implacer; Q-Med AB, Uppsala, Sweden) is used to deliver the bulking agent in the outpatient clinic setting without need for endoscopy. An industry-sponsored (Q-Med) randomized noninferiority trial (2009) conducted in North America compared the Zuidex system plus the Implacer with Contigen. Patients were blinded to treatment group. The primary study outcome was the proportion of women who had a 50% or greater reduction in urinary leakage on provocation testing from baseline to 12 months after the final treatment (up to 3 treatments were permitted). The primary outcome was achieved by 65% of Zuidex-treated women compared with 84% in the Contigen group; noninferiority of Zuidex was not established. The trial was limited by a high rate of missing data; primary outcomes data were missing for 35% of randomized patients.
A 2005 open multicenter study from Europe reported on a 12-month 77% positive response rate (reduction ≥50% for provocation test urinary leakage) with the dextranomer/hyaluronic acid (Zuidex system with Implacer) in 142 women who met strict inclusion and exclusion criteria. Similar to the North American trial, this study had a high dropout rate (24%), an unrepresentative patient population, and lacked a comparison group. Twenty-one women in this study were followed for a mean of 6.7 years after treatment with the Zuidex system. At this long-term follow-up, 7 (33%) of 21 were continent of urine, but 6 of the 7 had had other continence procedures since their Zuidex injections.

**Polyacrylamide Hydrogel (e.g., Bulkamid)**

Polyacrylamide hydrogel (Bulkamid; Contura International A/S, Søborg, Denmark) is a gel containing 2.5% cross-linked polyacrylamide and 97.5% pyrogenic water. A single RCT was identified that compared Bulkamid with an FDA-approved bulking agent (Contigen).

In 2014, Sokol et al reported on an RCT performed under an FDA-regulated investigational device exemption. This single-blind multicenter randomized non-inferiority trial compared Bulkamid with collagen gel (Contigen) in 345 women. Up to 3 injections were given. Patients completed the outcome measures at 1, 3, 6, 9, and 12 months after the last bulking procedure. The primary outcome measure was the responder rate at 12 months, determined by a composite of a 50% decrease in leakage, as measured by the 24-hour pad test, and a minimum 50% decrease in self-reported daily incontinence episodes. Bulkamid met the non-inferiority margin, with a minimum 50% decrease in leakage and incontinence episodes in 53% of patients in the hydrogel group and 55% of patients in the collagen gel group. At 12 months, 47% of patients treated with hydrogel and 50% of patients treated with collagen gel reported zero stress incontinence episodes.

Several case series, conducted in Europe, have been published. The largest (N=256) is by Pai and Al-Singary (2015). Women with stress or mixed urinary incontinence (>1 episode per 24 hours) who received injections of Bulkamid were assessed yearly with quality of life measured by visual analog scale and incontinence by the International Consultation on Incontinence Questionnaire. The primary outcome was whether patients were completely dry (cured) or leaked once a week or less (significant improvement). At the 3-month follow-up, 110 (42.9%) were cured and 102 (39.8%) patients reported significant improvement. These percentages were maintained through 5 years (median, 38 months). However, only 60 (23.4%) patients were available for follow-up at 60 months, limiting interpretation of the long-term results.

A 2010 multicenter series by Lose et al included 135 adult women with symptomatic stress (n=67) or mixed (n=68) incontinence. Eligibility included presence of symptoms for at least 12 months, including at least 1 episode of incontinence daily. Ninety-eight (73%) patients completed 12-month follow-up. The primary outcome was response to treatment, defined as patients self-reporting that they considered themselves “improved” or “cured.” The response rate was 71% at 6 months and 66% at 12 months. Corresponding cure rates were 16% and 24%. There were 32 treatment-related adverse effects including 2 cases of urinary retention requiring hospitalization and 10 cases of urinary tract infection.

A 2013 two-center prospective series included 82 women who had had stress incontinence for at least 12 months. Patients received an injection of Bulkamid, and non-responders were offered a second injection after 3 months. A total of 80 (98%) women were evaluated at 3 and 6 months, and 78 (95%) completed 1-year follow-up. The primary efficacy outcome was the subjective success rate at 1 year, defined as answering 1 or 2 on the Patient Global Improvement Impression questionnaire, which has a scoring range from 1 (very much better) to 7 (very much worse). In an intention-to-treat analysis, the subjective success rate at 1 year was 74% (61/82 patients). Seven patients reported no change, and none reported symptom worsening. At 1 year, 87% (71/78) of patients were considered to be...
Injectable Bulking Agents for the Treatment of Urinary and Fecal Incontinence

responders (answer of 1, 2 or 3 on the Patient Global Improvement Impression). Twenty-one (26%) patients had adverse events attributable to the injection procedure. The most common adverse event was urinary tract infection, reported by 8 patients. Four patients reported de novo urinary urgency; in all cases, this resolved by 3 months.

Eight-year outcomes were reported in 2014 for 24 women, of whom 15 (62.5%) had no further treatment, 1 received a second treatment with hydrogel, and 7 had placement of mid-urethral slings. Subjectively, 44% considered their incontinence to be cured or much improved. Vaginal ultrasonography showed visible hydrogel deposits in all patients.

**Polytetrafluoroethylene (e.g., Teflon)**
No published clinical trials were identified on polytetrafluoroethylene as a bulking agent.

**Bulking Agents Not Requiring FDA Approval**

**Autologous Fat and Autologous Ear Chondrocytes**
Other materials have been used as bulking agents but have not demonstrated the same sustained effectiveness as cross-linked collagen or carbon-coated beads. In a double-blind RCT of 56 women that compared peri-urethral injections of autologous fat (treatment group) with saline (placebo group), Lee et al (2001) found that peri-urethral fat injections were not more efficacious than placebo for treating stress incontinence. At 3 months, only 6 (22.2%) of 27 patients in the treatment group and 6 (20.7%) of 29 in the placebo group were cured or improved. In addition, 1 death occurred as a result of pulmonary fat embolism. In another clinical trial of 32 women, Bent et al (2001) reported that 50% of patients remained dry for 12 months after receiving a single outpatient injection of harvested autologous auricular cartilage. While autologous substances have a non-immunogenic advantage, their use may be limited by resorption and fibrous replacement along with local discomfort associated with harvesting procedures.

**Autologous Cellular Therapy**
In 2007, Strasser et al published the first RCT on autologous cell therapy for treating SUI. While widely cited as an important advance in the field, the *Lancet* retracted publication of this trial in 2008 due to ethical and quality concerns. The *Lancet* retraction stated: “…in our view, the conclusions of this official investigation pinpoint so many irregularities in the conduct of their (Strasser et al) work that, taken together, the paper should be retracted from the public record.”

Pooled data from 80 patients in 2 phase 1/2 dose-response trials from Cook MyoSite were reported in 2014. A phase 3 trial (NCT01382602) with 150 patients was completed in January 2017.

**Section Summary: Urinary Incontinence**
A number of RCTs and a Cochrane review of RCTs evaluating periurethral bulking agents for the treatment of urinary incontinence have been published. The trials vary by bulking agents used and comparator interventions (e.g., placebo, conservative therapy, another bulking agent). Due to this heterogeneity across studies, and the small number of studies in each category, Cochrane reviewers were unable to draw specific conclusions about the efficacy of specific bulking agents compared with alternative treatments. Cross-linked collagen is the most well established bulking agent, but it was withdrawn from the market. Results from available trials have suggested that carbon-coated spheres, calcium hydroxylapatite, and polydimethylsiloxane have efficacy for treating incontinence that is similar to cross-linked collagen. For other agents (e.g., autologous cellular therapy, autologous fat, autologous ear chondrocytes, Teflon), there are few RCTs and little evidence of efficacy.
Fecal Incontinence

Systematic Reviews
A 2016 comparative effectiveness review for the Agency for Healthcare Research and Quality evaluated treatments for fecal incontinence. Reviewers found low strength of evidence from 2 RCTs that dextranomer anal bulking injections (NASHA Dx, Solesta) were more effective than sham injections on some outcome measures (i.e., 50% reduction in episodes, number of incontinence-free days, quality of life) but not more effective than sham on fecal incontinence severity or frequency, and no more effective than pelvic floor muscle training with biofeedback on fecal incontinence severity or quality of life. There was moderate strength of evidence from 2 RCTs comparing Durasphere with a non-FDA-approved bulking agent that off-label use of Durasphere reduced fecal incontinence severity for up to 6 months, with diminishing improvements after that time.

In 2013, Cochrane updated a review of perianal injectable bulking agents for treating fecal incontinence. Reviewers identified 5 RCTs (total N=382 patients) comparing bulking agents with placebo, no intervention, or an alternative intervention. The 5 trials all included adults with internal anal sphincter dysfunction or passive fecal incontinence who had failed previous conservative treatments (eg, pelvic floor muscle training). One of the 5 trials, detailed next, used the FDA-approved bulking agent dextranomer in stabilized hyaluronic acid (marketed as Solesta). Two trials used a placebo or sham control, two compared different bulking agents, and the fifth trial compared two methods of injecting the same agent. Length of follow-up ranged from 3 to 12 months. Four trials were judged to be of high or uncertain risk of bias. The greatest potential source of bias was lack (or unclear) blinding of outcome assessment and lack of blinding of surgeons performing the procedure. Due to heterogeneity among trials, study findings were not pooled. Overall, conclusions on efficacy were limited by the small number of RCTs identified, most of which had methodologic limitations, and a lack of long-term follow-up.

Previously, in 2011, 2 systematic reviews were published that included observational studies and RCTs evaluating bulking agents for treating fecal incontinence. Hussain et al included 1070 patients from 39 studies in a safety analysis. Adverse events occurred in 139 (13.5%) patients. The most common complication was pain, which occurred in 67 (6.5%) patients, followed by leakage of injected material, which was reported by 58 (5.6%) patients. Reviewers did not report the number of serious adverse events.

Randomized Controlled Trials
The RCT evaluating Solesta, included in the 2011 Cochrane review, was an industry-sponsored multicenter trial (2011) that compared Solesta with sham treatment in 206 adults. To be eligible for inclusion, patients had to have a Cleveland Clinic Florida Fecal Incontinence Score of 10 or higher, at least 4 documented incontinence episodes in 2 weeks, symptoms for at least 12 months, and failure of at least 1 medically supervised conservative treatment (which could include dietary modification, fiber supplements, or loperamide hydrochloride). Patients received an initial injection, and those with persistent symptoms and no substantial adverse effects at 1 month were offered a second injection. A total of 112 (86%) patients in the active treatment group and 61 (87%) patients in the sham group received a second procedure. Response to treatment was defined as a reduction in the number of incontinence episodes by 50% or more compared with baseline. The trial was double-blind for the first 6 months of follow-up; at 6 months, patients in the sham group were offered active treatment. Thus, the primary efficacy outcome was assessed at 6 months.

A total of 197 (96%) of 206 randomized patients completed 6-month follow-up and were included in the primary efficacy analysis. Seventy-one (52%) in the active treatment group and 22 (31%) in the sham
Injectable Bulking Agents for the Treatment of Urinary and Fecal Incontinence

group had a 50% or greater reduction in incontinence episodes at 6 months. The difference between groups was statistically significant (odds ratio, 2.36; 95% confidence interval, 1.24 to 4.47; p=0.009). Findings on secondary outcomes at 6 months were mixed. For example, the mean increase in number of incontinence-free days was significantly higher in the active treatment group (3.1) than the sham group (1.7; p=0.016), but the median decrease in number of incontinence episodes did not differ significantly between groups (6.0 vs 3.0, respectively; p=0.09). Moreover, change in the Cleveland Clinic Florida Fecal Incontinence Score did not differ significantly between groups at 6 months; (2.5 points for active treatment vs 1.7 points for sham treatment). Quality of life was measured by the Fecal Incontinence Quality of Life instrument, which has 4 subscales. One of the 4 subscales (coping and behavior) improved significantly more in the treatment group than in the sham group at 6 months. Change in scores on the other 3 subscales (lifestyle, depression and self-perception, embarrassment) did not differ significantly between groups at 6 months. Trialists did not report the proportion of patients continent at follow-up, either as a primary or secondary outcome.

During the 6-month blinded treatment phase, 128 adverse events were reported in the active treatment group and 29 in the sham group. The most common adverse event in the active treatment group was proctalgia, which occurred in 19 (14%) patients. In contrast, 2 (3%) patients in the sham group reported proctalgia. Moreover, 10 (7%) patients in the active treatment group and 1 (1%) patient in the sham group had rectal hemorrhage. Injection-site bleeding occurred in 12 (17%) patients in the sham group and in 7 (5%) patients in the active treatment group. Two serious adverse events were reported, both in the active treatment group (one rectal abscess and one prostate abscess).

Subsequent to the Cochrane reviewers’ search of the literature, Dehli et al (2013) in Norway published findings of an RCT evaluating Solesta. A total of 126 adults with fecal incontinence were randomized to injectable bulking agents (n=62) or a 6-month biofeedback intervention (n=64). Patients in the bulking agent group who reported minor or no symptom improvement at 3 months received a second injection. The primary efficacy outcome was incontinence severity, as measured by the St. Mark’s Fecal Incontinence Grading System score, which can range from 0 (perfect continence) to 24 (maximal incontinence). A St. Mark’s score of at least 4 was required for study participation. Ten (8%) patients dropped out of the study before 6 months. At the 6-month follow-up, the mean St. Mark’s score in the biofeedback group had decreased from 12.6 points (95% CI, 11.4 to 13.8) at baseline to 9.2 points (95% CI, 7.9 to 10.5). In the bulking agents group, mean scores were 12.9 (95% CI, 11.8 to 14.0) at baseline and 8.9 (95% CI, 7.6 to 10.2) at 6 months. This difference between groups in St. Mark’s score reduction was not statistically significant. In addition, change in St. Mark’s score did not differ between groups at 24 months; only 61 (49%) patients completed the 24-month follow-up. Three of the first 10 patients in the bulking agent group developed infections at the injection site and underwent treatment; subsequent patients in this group received prophylactic antibiotics.

Another 2013 RCT, conducted in Australia, compared 2 bulking agents for fecal incontinence. Neither bulking agent was FDA-approved for use in the United States. The trial was terminated early because one of the agents was removed from the Australian Pharmaceutical Benefits Scheme. The trial found no difference in efficacy between agents. The trial lacked a comparison group of patients not receiving bulking agents, which limits the ability to draw conclusions about the relative efficacy of bulking agents to sham or alternative treatments.

Uncontrolled Trials
Longer term data on Solesta are available from an uncontrolled study (2013) conducted in Spain. A total of 115 patients with fecal incontinence received 4 injections of Solesta. Eighty-three (72%) of 115 patients completed the 24-month follow-up. The primary efficacy end point was response to treatment,
defined as a minimum 50% reduction from baseline in the number of fecal incontinence episodes recorded in a 28-day diary. At the 24-month follow-up, 52 (63%) of 83 patients with data available had responded to treatment. The median number of incontinence-free days in a 28-day period increased from 14.6 at baseline to 21.7 at 24 months. The study lacked a comparison group and had a high dropout rate.

Section Summary: Fecal Incontinence

Several RCTs and systematic reviews of RCTs on bulking agents for the treatment of fecal incontinence have been published. A 2016 comparative effectiveness review from the Agency for Healthcare Research and Quality evaluated 2 RCTs with the FDA-approved product NASHA Dx (Solesta) and 2 RCTs with Durasphere. One RCT using NASHA Dx found that, compared with sham, NASHA Dx improved some outcomes but not others. The other RCT did not find a significant difference in efficacy between NASHA Dx and biofeedback. Two additional RCTs with Durasphere (off-label in the U.S.) found short-term improvements in fecal incontinence severity. Overall, the evidence is not sufficient to conclude that bulking agents are an effective treatment for fecal incontinence. Corroboration of the single positive trial is needed, and controlled trials with longer follow-up are important to determine the durability of any treatment effect.

SUMMARY OF EVIDENCE

For individuals who have stress urinary incontinence who receive injectable bulking agents, the evidence includes RCTs and systematic reviews of RCTs. Relevant outcomes are symptoms, functional outcomes, quality of life, and treatment-related morbidity. Studies have shown that cross-linked collagen improves the net health outcome (i.e., it is effective in some patients who have failed conservative treatment with fewer adverse events than surgery), although products that cross-link in such a way are no longer commercially available. There is evidence that FDA-approved carbon-coated spheres, calcium hydroxylapatite, and polydimethylsiloxane have efficacy for treating incontinence, and further that they produce outcomes with a safety profile similar to cross-linked collagen. The evidence is sufficient to determine that the technology results in a meaningful improvement in the net health outcome.

For individuals who have fecal incontinence who receive injectable bulking agents, the evidence includes RCTs and systematic reviews of RCTs. Relevant outcomes are symptoms, functional outcomes, quality of life, and treatment-related morbidity. A comparative effectiveness review from the Agency for Healthcare Research and Quality evaluated 2 RCTs with the FDA-approved product NASHA Dx (Solesta) and 2 RCTs with Durasphere (off-label in the United States). One RCT comparing NASHA Dx with sham found that NASHA Dx improved some outcomes but not others. The other RCT did not find a significant difference in efficacy between NASHA Dx and biofeedback. Two additional RCTs evaluating Durasphere found only short-term improvements in fecal incontinence severity. Controlled trials with longer follow-up are important to determine the durability of any treatment effect. The evidence is insufficient to determine the effects of the technology on health outcomes.

SUPPLEMENTAL INFORMATION

CLINICAL INPUT FROM PHYSICIAN SPECIALTY SOCIETIES AND ACADEMIC MEDICAL CENTERS

While the various physician specialty societies and academic medical centers may collaborate with and make recommendations during this process, through the provision of appropriate reviewers, input received does not represent an endorsement or position statement by the physician specialty societies or academic medical centers, unless otherwise noted.

In response to requests, input was received from 4 physician specialty societies and 4 academic medical centers while this policy was under review in 2013. There was consensus agreement with all of the
policy statements among reviewers who provided responses. In particular, there was unanimous agreement among respondents for the statement that use of perianal bulking agents to treat fecal incontinence is considered investigational.

PRACTICE GUIDELINES AND POSITION STATEMENTS

American Urological Association et al
The 2017 joint guidelines on surgical treatment of female stress urinary incontinence from the American Urological Association and Society of Urodynamics, Female Pelvic Medicine and Urogynai Reckontruction stated that bulking agents are an option for patients considering surgery for stress urinary incontinence (SUI). The guidelines also stated that there are few long-term data on the efficacy of bulking agents and that retreatment is common.

European Urology Association and European Urogynaecological Association
A joint consensus review of data on implanted material for pelvic organ prolapse and stress urinary incontinence from the European Urology Association and European Urogynaecological Association stated: “Urethral balloons and injectables are not recommended as first-line therapy for SUI. Bulking agents are associated with lower cure rates of SUI when compared with colposuspension or autologous fascial slings.”

Society of Obstetricians and Gynaecologists of Canada
In 2010, the Society of Obstetricians and Gynaecologists of Canada published guidelines on the evaluation and treatment of recurrent urinary incontinence after pelvic floor surgery. The guidelines recommended that conservative management be used as first-line therapy; it further stated that patients with significantly decreased urethral mobility may be managed with peri-urethral bulking agents as one of several treatment options.

National Institute for Health and Care Excellence
In 2015, the National Institute for Health and Care Excellence updated its guidance on urinary incontinence in women. The updated guidance has recommended considering “intramural bulking agents (silicone, carbon-coated zirconium beads or hyaluronic acid/dextran copolymer) for the management of stress UI [urinary incontinence] if conservative management has failed. Women should be made aware that:

- repeat injections may be needed to achieve efficacy
- efficacy diminishes with time
- efficacy is inferior to that of synthetic tapes or autologous rectus fascial slings.”

In 2007, the Institute published guidance on injectable bulking agents for treating fecal incontinence. The guidance stated that there is insufficient evidence to support the safety and efficacy of injectable bulking agents for fecal incontinence, and that use of these products should take place in the context of a clinical trial.

American Society of Colon and Rectal Surgeons
In 2015, the American Society of Colon and Rectal Surgeons updated its practice parameters for the treatment of fecal incontinence. The Society gave a weak recommendation based on moderate-quality evidence (2B) that injection of bulking agents into the anal canal may help to decrease episodes of passive fecal incontinence. Studies reviewed showed modest short-term improvements, and no study identified showed a long-term benefit of bulking agents.
American College of Obstetricians and Gynecologists
In 2016, the American College of Obstetricians and Gynecologists updated its practice bulletin on urinary incontinence in women.\(^{38}\) The practice bulletin stated that “urethral bulking injections are a relatively noninvasive treatment for stress urinary incontinence that may be appropriate if surgery has failed to achieve adequate symptom reduction, if symptoms recur after surgery, in women with symptoms who do not have urethral mobility, or in older women with comorbidities who cannot tolerate anesthesia or more invasive surgery. However, urethral bulking agents are less effective than surgical procedures such as sling placement and are rarely used as primary treatment for stress urinary incontinence.” There was insufficient evidence to recommend any specific bulking agent.

U.S. PREVENTIVE SERVICES TASK FORCE RECOMMENDATIONS
Not applicable.

MEDICARE NATIONAL COVERAGE
The 1996 Medicare National Coverage Determination for Incontinence Control Devices (230.10) has addressed collagen implants but no other types of bulking agents.\(^ {39} \) Specific coverage information on collagen implants is as follows:

“Coverage of a collagen implant, and the procedure to inject it, is limited to the following types of patients with stress urinary incontinence due to ISD [intrinsic sphincteric deficiency]:

- Male or female patients with congenital sphincter weakness secondary to conditions such as myelomeningocele or epispadias;
- Male or female patients with acquired sphincter weakness secondary to spinal cord lesions;
- Male patients following trauma, including prostatectomy and/or radiation; and
- Female patients without urethral hypermobility and with abdominal leak point pressures of 100 cm H\(_2\)O or less.

Patients whose incontinence does not improve with 5 injection procedures (5 separate treatment sessions) are considered treatment failures, and no further treatment of urinary incontinence by collagen implant is covered. Patients who have a recurrence of incontinence following successful treatment with collagen implants in the past (e.g., 6-12 months previously) may benefit from additional treatment sessions. Coverage of additional sessions may be allowed but must be supported by medical justification.”

No national coverage determination was identified on injectable bulking agents for treating fecal incontinence.

ONGOING AND UNPUBLISHED CLINICAL TRIALS
Some currently unpublished trials that might influence this review are listed in Table 1.
