**DISCLAIMER/INSTRUCTIONS FOR USE**

Medical Policy provides general guidance for applying Blue Cross of Idaho benefit plans (for purposes of Medical Policy, the terms “benefit plan” and “member contract” are used interchangeably). Coverage decisions must reference the member specific benefit plan document. The terms of the member specific benefit plan document may be different than the standard benefit plan upon which this Medical Policy is based. If there is a conflict between a member specific benefit plan and the Blue Cross of Idaho’s standard benefit plan, the member specific benefit plan supersedes this Medical Policy. Any person applying this Medical Policy must identify member eligibility, the member specific benefit plan, and any related policies or guidelines prior to applying this Medical Policy. Blue Cross of Idaho Medical Policies are designed for informational purposes only and are not an authorization, explanation of benefits or a contract. Receipt of benefits is subject to satisfaction of all terms and conditions of the member specific benefit plan coverage. Blue Cross of Idaho reserves the sole discretionary right to modify all its Policies and Guidelines at any time. This Medical Policy does not constitute medical advice.

**POLICY**

Verteporfin photodynamic therapy as monotherapy may be considered **medically necessary** as a treatment of choroidal neovascularization (CNV) associated with age-related macular degeneration, pathologic myopia, presumed ocular histoplasmosis, chronic central serous chorioretinopathy, or choroidal hemangioma.

Verteporfin photodynamic therapy is considered **investigational** as monotherapy for other ophthalmologic disorders.

Verteporfin photodynamic therapy is considered **investigational** when used in combination with one or more of the antivasculer endothelial growth factor therapies: pegaptanib (Macugen®), ranibizumab (Lucentis®), bevacizumab (Avastin®), or aflibercept (Eylea™) as a treatment of CNV associated with age-related macular degeneration, pathologic myopia, presumed ocular histoplasmosis, central serous chorioretinopathy, choroidal hemangioma, or for other ophthalmologic disorders.

**POLICY GUIDELINES**

U.S. Food and Drug Administration (FDA) labeling for verteporfin indicates that the physician should reevaluate the patient every 3 months and, if choroidal neovascularization leakage is detected on fluorescein angiography, therapy should be repeated. However, total number of treatments is not addressed by FDA. Evidence defining when treatment should stop is not available, but experts have suggested stopping “when the situation is judged to be ‘futile’.“ FDA labeling states that the “safety and efficacy of Visudyne beyond 2 years have not been demonstrated.”
Acute central serous chorioretinopathy refers to self-limiting disease that resolves spontaneously over a few months without any treatment. Chronic central serous chorioretinopathy has been defined as a serous macular elevation, visible biomicroscopically or detected by optical coherence tomography, that is associated with retinal pigment epithelial atrophic areas and subtle leaks or ill-defined staining by fluorescein angiography; it does not resolve spontaneously within a few months.

Please see the Codes table for details.

**BENEFIT APPLICATION**

**BlueCard/National Account Issues**

State or federal mandates (eg, Federal Employee Program) may dictate that certain U.S. Food and Drug Administration-approved devices, drugs, or biologics may not be considered investigational, and thus these devices may be assessed only by their medical necessity.

**BACKGROUND**

**Vision Loss**

Severe vision loss can occur with ocular neovascularization, the growth of abnormal blood vessels in the retina or choroid. Neovascularization occurs in a number of ocular diseases, including age-related macular degeneration.

**Age-Related Macular Degeneration**

Age-related macular degeneration is a degenerative disease of the retina that results in loss of central vision. Two distinctive forms, known as dry and wet degeneration, may be observed. The dry form (also known atrophic or areolar) is more common and is often a precursor of the wet form (also known as exudative neovascular or disciform). The wet form is more devastating and characterized by serous or hemorrhagic detachment of the retinal pigment epithelium and development of choroidal neovascularization, which greatly increases the risk of developing severe irreversible loss of vision. Choroidal neovascularization is categorized as classic or occult. Classic choroidal neovascularization appears as an initial lacy pattern of hyperfluorescence followed by more irregular patterns as the dye leaks into the subretinal space. Occult choroidal neovascularization lacks the characteristic angiographic pattern. Classic choroidal neovascularization carries a worse prognosis for vision than occult choroidal neovascularization, suggesting that the proliferative response that obscures new vessels may also favorably alter the clinical course of age-related macular degeneration.

**Pathologic Myopia**

Pathologic myopia refers to an abnormal elongation of the eye associated with severe near-sightedness. It generally occurs among people older than 30 years of age and can result in a progressive, severe loss of vision, frequently related to the development of choroidal neovascularization. Verteporfin photodynamic therapy has also been investigated in patients with choroidal neovascularization related to pathologic myopia. Antivascular endothelial growth factor therapy is now considered a first-line intervention in patients with myopic choroidal neovascularization.
**Presumed Ocular Histoplasmosis**

Presumed ocular histoplasmosis may be the second most common cause of blindness in patients younger than 50 years of age in certain endemic areas (Ohio and Mississippi River Valleys in the United States). This condition is characterized by a positive skin test for histoplasmosis, miliary opacities of the lungs, tiny choroidal scars, peripapillary disruption of the choriocapillaris, and exudation or hemorrhage from choroidal lesions in or near the macula. The condition is asymptomatic and benign, unless the choroidal neovascularization lesions, which may develop many years after chorioretinal scarring has taken place, affect the macula.

**Central Serous Chorioretinopathy**

Central serous chorioretinopathy refers to an idiopathic disease in which there is a serous detachment of the macula due to leakage of fluid from the choriocapillaris through the retinal pigment epithelium. This condition is avascular; however, neovascularization can occur as a secondary complication. In most cases, central serous chorioretinopathy resolves spontaneously in 3 to 4 months. However, in a few cases, chronic progression or recurrence can lead to the progressive decline of visual acuity. Central serous chorioretinopathy has been treated with medication and laser photocoagulation, but these treatments have limited efficacy. Multiple definitions have been used in the literature to classify central serous chorioretinopathy as acute or chronic based cutoff time points (eg, persistent fluid for <3, 4 or 6 months) or less frequently based on the timing of treatment. For example, acute central serous chorioretinopathy defined as the first attempted treatment to improve visual acuity, and chronic central serous chorioretinopathy is defined as being refractory to treatment. Further, multiple verteporfin photodynamic therapy strategies that use either reduced-dose or half-fluency have been evaluated for the treatment of central serous chorioretinopathy because full-dose verteporfin photodynamic therapy used in age-related macular degeneration has shown a potentially higher risk of developing choroidal ischemia and retinal atrophic changes.

**Polypoidal Choroidal Vasculopathy**

Polypoidal choroidal vasculopathy arises primarily from abnormal choroidal circulation, resulting in characteristic lesions comprising well-defined vascular networks of vessels ending in polyp-like structures. A less common subtype is polypoidal choroidal neovascularization, and it may be considered a subtype of age-related macular degeneration. Eyes that develop a cluster of grape-like polypoidal dilations are at high risk for severe vision loss.

**Choroidal Hemangioma**

Choroidal hemangioma is an uncommon, benign vascular tumor, manifesting as an orange-red mass in the posterior pole of the eye. Visual loss may be progressive and irreversible because of chronic foveal detachment.

**Angioid Streaks**

Angioid streaks result from crack-like breaks in the Bruch membrane (the innermost layer of the choroid) and occur in patients spontaneously or due to blunt trauma or associated with some systemic
diseases such as pseudoxanthoma elasticum, Paget disease of bone, or sickle hemoglobinopathy. Vision loss in eyes with angioid streaks occurs most frequently as a result of choroidal neovascularization.

**Treatment**

Available therapeutic options for choroidal neovascularization include antivascular endothelial growth factor inhibitors, verteporfin photodynamic therapy, antioxidants, thermal laser photocoagulation, and corticosteroids. The safety and efficacy of each treatment depends on the form and location of the neovascularization.

Verteporfin photodynamic therapy is a treatment modality designed to selectively occlude ocular choroidal neovascular tissue. The therapy is a 2-step process, consisting of an injection of the photosensitizer verteporfin, followed 15 minutes later by laser treatment to the targeted sites of retinal neovascularization. The laser treatment selectively damages the vascular endothelium and occludes the neovascularized tissue. Patients may be retreated if leakage from choroidal neovascularization persists.

Monotherapy with vascular endothelial growth factor inhibitors is now standard treatment of choroidal neovascularization due to age-related macular degeneration and pathologic myopia. Combining verteporfin photodynamic therapy with antivascular endothelial growth factor inhibitors, concurrently or sequentially, has a biologic basis and has been investigated in multiple trials particularly in the treatment of choroidal neovascularization due to age-related macular degeneration and pathologic myopia.

**Regulatory Status**

In 2000, verteporfin (Visudyne®; Novartis), an intravenous photodynamic therapy agent, was approved by the U.S. Food and Drug Administration for the treatment of age-related macular degeneration in patients with predominantly classic subfoveal choroidal neovascularization. Subsequently, in 2001, the indication was expanded to include presumed ocular histoplasmosis and pathologic myopia.

**RATIONALE**

This evidence review was created in December 2000 and has been updated regularly with searches of the MEDLINE database. The most recent literature update was performed through January 3, 2020.

Evidence reviews assess the clinical evidence to determine whether the use of a technology improves the net health outcome. Broadly defined, health outcomes are length of life, quality of life, and ability to function including benefits and harms. Every clinical condition has specific outcomes that are important to patients and to managing the course of that condition. Validated outcome measures are necessary to ascertain whether a condition improves or worsens; and whether the magnitude of that change is clinically significant. The net health outcome is a balance of benefits and harms.

To assess whether the evidence is sufficient to draw conclusions about the net health outcome of a technology, 2 domains are examined: the relevance and the quality and credibility. To be relevant, studies must represent one or more intended clinical use of the technology in the intended population and compare an effective and appropriate alternative at a comparable intensity. For some conditions, the alternative will be supportive care or surveillance. The quality and credibility of the evidence depend
on study design and conduct, minimizing bias and confounding that can generate incorrect findings. The randomized controlled trial (RCT) is preferred to assess efficacy; however, in some circumstances, nonrandomized studies may be adequate. RCTs are rarely large enough or long enough to capture less common adverse events and long-term effects. Other types of studies can be used for these purposes and to assess generalizability to broader clinical populations and settings of clinical practice. The following is a summary of the key literature to date.

**Age-Related Macular Degeneration**

The use of verteporfin photodynamic therapy in choroidal neovascularization has decreased substantially with the availability of antivascular endothelial growth factor therapy. Subsequent to U.S. Food and Drug Administration (FDA) approval of verteporfin photodynamic therapy in 2000, the FDA approved pegaptanib in 2004 and ranibizumab in 2006 for treatment of age-related macular degeneration related choroidal neovascularization. The approval of pegaptanib was based on a sham-controlled RCT\(^1,2\), while ranibizumab was approved based on a head-to-head comparison with verteporfin photodynamic therapy in the Anti-VEGF Antibody for the Treatment of Predominantly Classic Choroidal Neovascularization in Age-Related Macular Degeneration (ANCHOR) trial.\(^3\) Intravitreal injections of antivascular endothelial growth factor drugs such as ranibizumab and bevacizumab have shown superior efficacy compared with verteporfin photodynamic therapy in multiple head-to-head trials. Currently, verteporfin photodynamic therapy is used for patients in whom vascular endothelial growth factor inhibitors are contraindicated or for those who fail to benefit from vascular endothelial growth factor inhibitors.

**Verteporfin Photodynamic Therapy vs Placebo**

A TEC Assessment (2000) concluded that fewer patients treated using verteporfin photodynamic therapy compared with placebo experienced a clinically significant loss of visual acuity (38.8% vs 53.6%, respectively; \(p<0.001\)).\(^4\) These conclusions were based on the 1-year follow-up results of 609 patients enrolled in 2 similar, multicenter, double-masked, randomized placebo-controlled trials called TAP published in 1999.\(^5\) Subgroup analysis showed that efficacy was limited to patients in whom the area of classic choroidal neovascularization occupied 50% or more of the area of the lesion. Subsequently, in 2001, 2-year results of the Treatment of Age-Related Macular Degeneration with Photodynamic Therapy (TAP) trials showed that beneficial outcomes for visual acuity and contrast sensitivity observed after 1-year of follow-up were sustained through 24 months.\(^6\) At 2 years, 53% of the verteporfin photodynamic therapy arm compared with 38% of the placebo arm lost fewer than 15 letters. Further, an average number of verteporfin photodynamic therapy treatments required was lower in the second year (2.2) compared with the first year (3.4). Subgroup analysis confirmed the earlier findings that efficacy was limited to patients in whom the area of classic choroidal neovascularization occupied 50% or more of the area of the lesion.

Since 2001, several additional reports from the TAP trials have been published.\(^7,8,9\) They demonstrated positive outcomes with the use of verteporfin photodynamic therapy for subfoveal choroidal neovascularization, and further supported the findings of the earlier TAP trial reports. Kaiser (2006) reported on results of a 3-year open-label extension of the TAP trials.\(^10\) Of 402 verteporfin photodynamic therapy treated patients who completed the 24-month randomized study, 320 (80%) enrolled in the extension protocol. Of the 320 enrolled, 193 (60%) completed the 60-month examination, 122 (38%) discontinued prematurely, and 3 (1%) were noncompliant. Yearly treatment
rates declined from 3.5 treatments in the first year to 0.1 in the fifth year; patients who remained in the study lost an additional 2.3 lines of letters over the 3-year extension.

The Verteporfin in Photodynamic Therapy (VIP) trial (2001) randomized 339 patients to verteporfin photodynamic therapy or placebo. Most (76%) patients had occult disease while the remainder had early classic choroidal neovascularization with good visual acuity. The primary outcome was the proportion of eyes with fewer than 15 letters of visual acuity loss. While there was no significant difference between the treatment and placebo groups at 12 months, by 24 months a significantly lower percentage of those with occult choroidal neovascularization who were treated with verteporfin photodynamic therapy (55%) had lost vision compared with those who received placebo (68%; p=0.032). These results contrast with those of the TAP trials, although the patient populations differed. The TAP trials required all patients to have some percentage of classic choroidal neovascularization, while the VIP trial recruited patients with occult disease without evidence of classic choroidal neovascularization. In addition, the VIP trial required patients with occult disease to have experienced recent deterioration in vision. Results for the subgroup of patients with classic choroidal neovascularization but good visual acuity were not reported separately.

Multiple systematic reviews and meta-analysis have included TAP and VIP trials and corroborated the treatment benefit of verteporfin photodynamic therapy in preventing vision loss. A Cochrane review (2003) concluded that verteporfin photodynamic therapy was effective at preventing vision loss in classic and occult choroidal neovascularization due to age-related macular degeneration. In a meta-analysis of the safety of verteporfin photodynamic therapy, Azab et al (2004) analyzed data from the 24-month TAP A and B and VIP trials (total N=948 patients with age-related macular degeneration). Reviewers concluded that the safety profile of verteporfin photodynamic therapy did not differ statistically from placebo. An updated Cochrane review (2007) evaluated results from the 3 RCTs (total N=1022 patients), which included the TAP and VIP trials. Meta-analysis showed a 24-month risk ratio of losing 6 or more lines of visual acuity of 0.62 compared with the control group. Reviewers concluded that verteporfin photodynamic therapy was probably effective for treating choroidal neovascularization due to age-related macular degeneration, although the effect size was uncertain.

The result of a multicenter RCT (2008) that compared 2 intensities of initial verteporfin photodynamic therapy—every 2 or 3 months for first 6 months in 203 patients with choroidal neovascularization caused by age-related macular degeneration—showed no differences in overall outcomes for visual acuity or anatomic lesion features.

**Section Summary: Verteporfin Photodynamic Therapy vs Placebo**

The evidence for the efficacy of verteporfin photodynamic therapy includes multiple RCTs that have established its superiority over placebo. However, the efficacy is limited to a subgroup of patients with classic choroidal neovascularization. The use of verteporfin photodynamic therapy has now been largely replaced by antivascular endothelial growth factor therapies.

**Verteporfin Photodynamic Therapy Plus Anti-Vascular Endothelial Growth Factor Therapy**

Because verteporfin photodynamic therapy and ranibizumab target different disease components of age-related macular degeneration, it has been hypothesized that combining them might lead to a synergistic effect, with a decreased need for monthly vascular endothelial growth factor injection and
increased the durability of response while maintaining visual acuity. The open-label, phase 2 study (2006) demonstrated that same-day administration of ranibizumab and verteporfin photodynamic therapy was well tolerated and vision was maintained.\textsuperscript{10} Results of the phase 1/2 FOCUS (Intravitreal Injections of rhuFab V2 in Combination With Visudyne in Subjects With Age Related Macular Degeneration) trial further supported the idea that combination treatment might be more effective than monotherapy.\textsuperscript{15,16} In this trial, 162 patients with classic choroidal neovascularization secondary to age-related macular degeneration were randomized to verteporfin photodynamic therapy plus ranibizumab (n=106) or verteporfin photodynamic therapy plus sham (n=56). Verteporfin photodynamic therapy was repeated only if fluorescein angiography revealed persistent or recurrent leakage from choroidal neovascularization at evaluation visits (3-month intervals). Intention-to-treat analysis showed an average improvement in acuity of 5 letters at both 12 and 24 months (85% retention) with ranibizumab compared with a decrease of 8 letters in the verteporfin photodynamic therapy alone group. Visual acuity improved by 15 or more letters in 25% of patients treated with ranibizumab (plus verteporfin photodynamic therapy as needed) compared with 7% of patients treated with verteporfin photodynamic therapy alone. However, the FOCUS trial did not include a ranibizumab monotherapy arm.

Subsequently, the 2 larger phase 3 confirmatory trials - DENALI and MONT BLANC - failed to show the superiority of ranibizumab plus verteporfin photodynamic therapy over ranibizumab alone. DENALI (Efficacy/Safety of Verteporfin Photodynamic Therapy and Ranibizumab Compared with Ranibizumab in Patients with Subfoveal Choroidal Neovascularization) was a multicenter, double-masked, randomized phase 3b trial (2012) that tested the noninferiority of ranibizumab plus verteporfin photodynamic therapy vs verteporfin photodynamic therapy alone. In this trial, patients were randomized to ranibizumab plus standard fluence verteporfin photodynamic therapy (n=104) or reduced-fluence (n=105) or ranibizumab plus sham verteporfin photodynamic therapy (n=112).\textsuperscript{17} Patients received 3 consecutive monthly injections of ranibizumab followed by as-needed retreatments. The 2 main outcome measures were change in best-corrected visual acuity from baseline and the proportion of patients in the combination therapy groups with a treatment-free interval of 3 months or more. An improvement in mean best-corrected visual acuity score was observed in all treatment groups, with the largest mean change from baseline in the ranibizumab monotherapy group. The mean change in best-corrected visual acuity at 12 months was +5.3, +4.4, and +8.1 for ranibizumab plus standard fluence verteporfin photodynamic therapy, ranibizumab plus reduced-fluence verteporfin photodynamic therapy, and ranibizumab plus sham verteporfin photodynamic therapy, respectively. Noninferiority for visual acuity was not demonstrated. Trials failed to demonstrate the superiority of combination treatment to reduce treatment-free interval period. The proportion of patients with a treatment-free interval of 3 months or more was 92.6% (95% confidence interval [CI], 85.4% to 97.0%) in the ranibizumab plus standard fluence verteporfin photodynamic therapy and 83.5% (95% CI, 74.6% to 90.3%) in the reduced-fluence arm. Percentages for ranibizumab monotherapy were not reported.

MONT BLANC (Verteporfin Photodynamic Therapy Administered in Conjunction With Ranibizumab in Patients With Subfoveal Choroidal Neovascularization Secondary to Age-related Macular Degeneration) was similar to DENALI regarding design and outcome measures, except that the former did not include a reduced-fluence verteporfin photodynamic therapy arm.\textsuperscript{18} In this trial, 255 patients were randomized to ranibizumab plus standard fluence verteporfin photodynamic therapy (n=122) or ranibizumab plus sham verteporfin photodynamic therapy (n=133). Patients received 3 consecutive monthly injections of ranibizumab followed by as-needed retreatments. A difference in mean best-corrected visual acuity within 7 letters was designated as noninferiority margin. The mean change in best-corrected visual
Acuity at 12 months was +2.5 letters in ranibizumab plus standard fluence verteporfin photodynamic therapy group and +4.4 letters in the ranibizumab plus sham verteporfin photodynamic therapy group, yielding a mean difference (MD) of 1.88. Because this difference was within the noninferiority margin, authors concluded that ranibizumab plus verteporfin photodynamic therapy was noninferior to verteporfin photodynamic therapy alone. At 12 months, the proportion of patients with a treatment-free interval of 3 months or more was similar in the 2 groups (96% combination therapy vs 92% monotherapy). With the sample size of 125 in each arm, the trial as designed had 80% power to identify treatment difference of 20% or more in the proportion of patients with 3 or more months of treatment-free interval in the combination arm vs monotherapy arm. After 12 months, the proportion of patients with 3 or more months of treatment-free interval was 96% and 92% in the combination and monotherapy arm, respectively (difference in proportion, 0.04; 95% CI, -0.02 to 0.09). Thus, the trial failed to show the superiority of ranibizumab plus verteporfin photodynamic therapy over verteporfin photodynamic therapy alone in increasing the treatment-free interval.

A systematic review (2015) of antivascular endothelial growth factor injections for treating wet age-related macular degeneration compared antivascular endothelial growth factor monotherapy with antivascular endothelial growth factor combination therapy plus verteporfin photodynamic therapy. Results showed a significant difference in best-corrected visual acuity of 2.74 letters (95% CI, 0.26 to 5.21 letters; p=0.03) in favor of the monotherapy group (note that the conclusions of this systematic review indicated that the difference favored the combination group, which is incorrect). There were no differences between groups on the central retinal thickness or lesion size. Reviewers did not report a combined analysis of the number of antivascular endothelial growth factor injections performed in each group. Similar results were reported in a meta-analysis published in 2016.

In addition to the above trials, several smaller randomized trials have been published. Semeraro et al (2015) published an RCT evaluating 75 patients with treatment-naive exudative choroidal neovascularization due to age-related macular degeneration. Patients were randomized into 3 groups: ranibizumab monotherapy, ranibizumab plus reduced-fluence verteporfin photodynamic therapy, and ranibizumab plus ketorolac eye drops. At the 12-month follow-up, best-corrected visual acuity was superior in the ranibizumab plus ketorolac group (-0.25 logarithm of the minimum angle of resolution) compared with ranibizumab monotherapy (-0.14 logarithm of the minimum angle of resolution) or ranibizumab combined with verteporfin photodynamic therapy (-0.10 logarithm of the minimum angle of resolution). In a multicenter, unmasked trial, Williams et al (2012) randomized 60 patients to ranibizumab with half-fluence verteporfin photodynamic therapy or ranibizumab alone. Best-corrected visual acuity improved by 9.9 letters in the ranibizumab group and by 2.6 letters in the combined treatment group. The proportion of patients who gained 15 or more letters was 33% in the monotherapy arm and 31% in the combination arm. A small RCT by Lim et al (2012) assessed 31 patients with age-related macular degeneration and 10 patients with polypoidal choroidal vasculopathy who were randomized to bevacizumab monotherapy or bevacizumab plus verteporfin photodynamic therapy. At 12 months, the monotherapy and combined treatment groups showed similar improvements in best-corrected visual acuity and central foveal thickness, and the total number of bevacizumab injections was not reduced when verteporfin photodynamic therapy was given. A randomized, open-label assessor-blinded trial (2007) from Croatia with short-term (3-month) follow-up evaluated combination treatment with bevacizumab plus verteporfin photodynamic therapy (N=165 eyes). At 3-month follow-up, 22 (42%) of 52 patients improved by more than 0.2 logarithm of the minimum angle of resolution following combined treatment compared with 1 (2%) patient treated with bevacizumab alone and none treated with verteporfin photodynamic therapy alone.
Data from a retrospective study for adjunctive verteporfin photodynamic therapy in patients refractory to antivascular endothelial growth factor monotherapy has suggested a favorable effect on visual acuity and anatomic outcomes. Lee and Lee (2016) reported on data from a retrospective analysis of 28 eyes of 28 patients who showed persistent subretinal and/or intraretinal fluid after at least 4 antivascular endothelial growth factor injections in the 6 months before adjunctive verteporfin photodynamic therapy and subsequently received additional verteporfin photodynamic therapy and antivascular endothelial growth factor therapies. Patient charts were reviewed until 12 months after the initial verteporfin photodynamic therapy. During a 1-year follow-up, 17 (60.7%) eyes did not demonstrate recurrent fluid accumulation. Among the 11 eyes requiring retreatment, 7 eyes initially showed complete fluid absorption after the initial photodynamic therapy. At 12 months, best-corrected visual acuity had improved by 0.3 logarithm of the minimum angle of resolution or more or was maintained compared with baseline in 27 (96.4%) eyes.

Section Summary: Verteporfin Photodynamic Therapy Plus Anti-Vascular Endothelial Growth Factor Therapy

The evidence for the efficacy of verteporfin photodynamic therapy plus antivascular endothelial growth factor therapies compared with antivascular endothelial growth factor therapies alone includes 2 confirmatory RCTs (and their multiple analyses), multiple smaller RCTs, and a meta-analysis. This evidence does not demonstrate improvements in best-corrected visual acuity with combination therapy compared with antivascular endothelial growth factor monotherapy. Combination therapy may reduce the number of intravitreal injections needed, but this result has not been consistently reported across studies.

Verteporfin Photodynamic Therapy Plus Corticosteroids and/or Vascular Endothelial Growth Factor Inhibitors

Three RCTs have evaluated the combination of verteporfin photodynamic therapy with corticosteroids trial from Italy, 1 trial from Canada (Canadian Retinal Trials Group), and 1 trial from Iran. The Italian RCT (2008) assigned 84 treatment-naive patients with exudative age-related macular degeneration to verteporfin photodynamic therapy alone (n=41) or combination intravitreal triamcinolone acetonide plus verteporfin photodynamic therapy (n=43). Mean visual acuity increased at 1 month of follow-up but decreased progressively by the 24-month point in both groups. In the Canadian Retinal Trials Group study (2009), 100 patients with choroidal neovascularization due to age-related macular degeneration were randomized to verteporfin photodynamic therapy alone or verteporfin photodynamic therapy plus intravitreal triamcinolone. Combination treatment did not result in a significant difference in the primary outcome of visual acuity at 1 year compared with verteporfin photodynamic therapy alone. The Iranian trial (2014) randomized 84 treatment-naive patients who had choroidal neovascularization due to age-related macular degeneration to verteporfin photodynamic therapy plus bevacizumab with and without intravitreal triamcinolone. There were no significant differences in the best-corrected visual acuity at week 12 and other time points.

Section Summary: Verteporfin Photodynamic Therapy Plus Corticosteroids and/or Vascular Endothelial Growth Factor Inhibitors

The evidence for the efficacy of triple therapy verteporfin photodynamic therapy plus corticosteroid and antivascular endothelial growth factor includes 3 small RCTs. This evidence does not demonstrate
improvements in best-corrected visual acuity with this therapy compared with antivascular endothelial growth factor monotherapy. Comparative trials are needed to evaluate the efficacy of this triple therapy.

Pathologic Myopia

The initial evidence on pathologic myopia was based primarily on retrospective studies and clinician experience. RADIANCE (Efficacy and Safety of Ranibizumab in Patients With Visual Impairment Due to Choroidal Neovascularization Secondary to Pathologic Myopia), a multicenter RCT (2014) compared intravitreal ranibizumab with verteporfin photodynamic therapy in the treatment of myopic choroidal neovascularization and reported improved visual acuity at 12 months in the ranibizumab treatment arm. Zhu et al (2016) published a Cochrane review that found treatment with antivascular endothelial growth factor therapies was more likely to restore visual acuity than verteporfin photodynamic therapy.

Verteporfin Photodynamic Therapy vs Placebo

A second arm of the VIP trial focused on 120 patients with pathologic myopia and choroidal neovascularization, either classic, occult, or mixed (although 90% of patients had classic choroidal neovascularization), who were randomized 2:1 to verteporfin photodynamic therapy or placebo. Patients received an average of 3.4 verteporfin photodynamic therapy treatments over 12 months. The primary outcome was the proportion of eyes with fewer than 8 letters of visual acuity loss at 12 months by intention-to-treat analysis. At month 12, 58 (72%) of patients who received verteporfin photodynamic therapy lost fewer than 8 letters on a standard eye chart and 17 (44%) receiving placebo. Improvement of at least 5 letters was observed in 26 (32%) verteporfin photodynamic therapy-treated eyes compared with 6 (15%) placebo-treated eyes. Fluorescein angiography showed the progression of classic choroidal neovascularization in 36% of verteporfin photodynamic therapy-treated eyes compared with 54% of the placebo group. Trialists concluded that verteporfin photodynamic therapy increased the chance of stabilizing or improving vision compared with placebo for at least 1 year. However, the results at 2 years of follow-up were not statistically significant in favor of verteporfin photodynamic therapy.

Section Summary: Verteporfin Photodynamic Therapy vs Placebo

The evidence for the efficacy of verteporfin photodynamic therapy compared with placebo includes a subgroup analysis from a large RCT. This analysis showed verteporfin photodynamic therapy to be more effective than placebo in preventing vision loss, and these findings have been corroborated in nonrandomized studies. However, the long-term efficacy of verteporfin photodynamic therapy is uncertain. Moreover, use of verteporfin photodynamic therapy for myopic choroidal neovascularization has now been largely replaced by antivascular endothelial growth factor therapies.

Verteporfin Photodynamic Therapy Plus Anti-Vascular Endothelial Growth Factor Therapy

Rinaldi et al (2017) randomized 60 patients to verteporfin photodynamic therapy (standard- and reduced-fluence, n=20 each) plus ranibizumab or to ranibizumab monotherapy (n=20). The primary outcomes were mean change in best-corrected visual acuity and mean change in retinal thickening from baseline to week 48. The trial was likely underpowered to detect a clinical meaningful difference in best corrected visual acuity for between-group comparisons. Mean best-corrected visual acuity change at 48
weeks was +0.2 and +15 letters with standard- and reduced-fluence verteporfin photodynamic therapy plus ranibizumab, respectively, compared with +16.8 letters with ranibizumab monotherapy. At 48 weeks, mean central foveal thickness decreased from baseline was 58 μm, 91.4 μm, and 85 μm for the 3 groups, respectively.

Chen et al (2011) compared bevacizumab monotherapy (n=17) with bevacizumab plus verteporfin photodynamic therapy (n=6) in a retrospective analysis of patients with choroidal neovascularization secondary to causes other than age-related macular degeneration; approximately half of the patients had myopic choroidal neovascularization. Most observed differences between groups were not statistically significant, likely due to the small sample size. For example, mean change in visual acuity at 12-month follow-up was 1.7 lines in the monotherapy group and 2.8 lines in the combination therapy group, and 36% of the monotherapy group gained 3 lines or more compared with 60% in the combination therapy group. The combination group received fewer reinjections (average injections, 2.6 vs 4.8), but this difference was not statistically significant (p=0.11). Subgroup analysis for cases of myopic choroidal neovascularization showed no significant difference between groups in mean acuity gains (2.0 lines in the monotherapy group vs 2.3 lines in the combination therapy group), with fewer reinjections (2 vs 7.2, p<0.05) needed in the combination group during the 12-month follow-up. No serious ocular complications were observed. Prospective comparison with a larger number of patients is needed.

**Section Summary: Verteporfin Photodynamic Therapy Plus Anti-Vascular Endothelial Growth Factor Therapy**

The evidence for the efficacy of verteporfin photodynamic therapy plus antivascular endothelial growth factor therapy includes a small RCT and a retrospective study. This evidence does not demonstrate improvements in best-corrected visual acuity. Comparative trials are needed to evaluate the efficacy of this combination therapy vs relevant comparators.

**Presumed Ocular Histoplasmosis**

There are few published data on the use of verteporfin photodynamic therapy to treat patients with choroidal neovascularization related to ocular histoplasmosis. The FDA approval of verteporfin photodynamic therapy for ocular histoplasmosis in 2001 was based on a prospective single-arm study involving 26 patients with ocular histoplasmosis. Visual acuity improved by an average of more than 1 line (6.7 letters) on a standard eye chart at 12 months, with 28% of patients experiencing improvement of at least 3 lines (15 letters). Visual acuity decreased by fewer than 3 lines in 88% of patients during the same period from a historical control. Ramaiya et al (2013) reported on results from a small RCT that assigned 19 patients to ranibizumab or photodynamic therapy with rescue ranibizumab. The primary outcome measure was the change in visual acuity at 1 year. Data from 10 of the 19 randomized patients were excluded from analysis because of lack of follow-up data. The number of injections in the ranibizumab arm was 7.7 (range, 1-11). The mean number of photodynamic therapy treatments administered was 2.5 (range, 2-3). All patients in the verteporfin photodynamic therapy group required rescue ranibizumab therapy, with a mean of 2.5 (range, 2-3) injections. Mean change in the Early Treatment Diabetic Retinopathy Study visual acuity at 1-year follow-up was 19.6 letters in the ranibizumab group and 21 letters in the photodynamic therapy group. Four (80%) of 5 patients showed a greater than 15 letter gain at 1 year in the ranibizumab group, whereas 1 of 2 patients in the verteporfin photodynamic therapy group showed a greater than 15 letter gain. Because of 50% lost to
follow-up, a small sample (<6 patients per arm), and incomplete reporting of the trial results, interpretation of data is difficult.

Section Summary: Presumed Ocular Histoplasmosis

The evidence for the efficacy of verteporfin photodynamic therapy includes a small prospective single-arm study and an RCT. Lack of a control arm in the single-arm study and 50% loss to follow-up in the RCT preclude a meaningful interpretation of the data on observed improvements in visual acuity. Comparative trials are needed to evaluate the efficacy of combination verteporfin photodynamic therapy plus antivascular endothelial growth factor therapy.

Central Serous Chorioretinopathy

A Cochrane review with network meta-analysis (2015) evaluated various treatments for central serous chorioretinopathy that included both acute and chronic central serous chorioretinopathy. Only RCTs were included. Pairwise (direct) comparison for verteporfin photodynamic therapy included antivascular endothelial growth factor vs verteporfin photodynamic therapy, antivascular endothelial growth factor plus 50% verteporfin photodynamic therapy vs 50% verteporfin photodynamic therapy alone, 50% verteporfin photodynamic therapy vs observation or sham treatment, and 30% verteporfin photodynamic therapy vs 50% verteporfin photodynamic therapy vs verteporfin photodynamic therapy. (Percentages refer to the dose of verteporfin used.) The primary outcome was visual acuity at 12 months. Low-quality evidence from a 2008 study (58 participants) suggested that half-dose verteporfin photodynamic therapy for acute central serous chorioretinopathy probably resulted in a small improvement in vision (MD = -0.10 logarithm of the minimum angle of resolution; 95% CI, -0.18 to -0.02 logarithm of the minimum angle of resolution) compared with sham treatment. Moderate-quality evidence from 2 studies suggested that 30% verteporfin photodynamic therapy results in a small improvement in vision compared with verteporfin photodynamic therapy (MD = -0.16 logarithm of the minimum angle of resolution; 95% CI, -0.22 to -0.10 logarithm of the minimum angle of resolution) and compared with 50% verteporfin photodynamic therapy (MD = -0.12 logarithm of the minimum angle of resolution; 95% CI, -0.15 to -0.08 logarithm of the minimum angle of resolution). Visual acuity scores at 12 months did not differ between antivascular endothelial growth and verteporfin photodynamic therapy or antivascular endothelial growth plus 50% verteporfin photodynamic therapy and 50% verteporfin photodynamic therapy alone, or 50% verteporfin photodynamic therapy and observation or sham treatment.

Acute Central Serous Chorioretinopathy

Chan et al (2008) conducted a double-masked, placebo-controlled trial of 63 patients who were randomized 2:1 to half-dose verteporfin photodynamic therapy or placebo. Thirty-nine patients in the verteporfin photodynamic therapy and 19 in the placebo arm completed the trial. The primary outcome measure (the proportion of eyes with the absence of subretinal fluid at the macula at 12 months) was observed in 37 (95%) eyes in the verteporfin photodynamic therapy arm and 11 (58%) eyes in the placebo arm. Mean increase of best-corrected visual acuity was 1.8 and 0.6 lines in the verteporfin photodynamic therapy and placebo arm, respectively. The treatment difference was 1.2 lines, which fell below the threshold of 3 lines considered clinically meaningful. A responder analysis was not reported.
Zhao et al (2015) reported on a double-masked, randomized, noninferiority trial with 131 patients that compared a 50% with a 30% dose of verteporfin photodynamic therapy for acute (<6 months) central serous chorioretinopathy. The 2 primary outcome measures were the proportion of eyes with complete absorption of subretinal fluid and the proportion of eyes with complete disappearance of fluorescein leakage at 6 and 12 months. At 12 months, the proportion of eyes with complete absorption of retinal fluid was 75.4% in the 30%-dose group and 94.6% in the half-dose group (p=0.004). Complete disappearance of fluorescein leakage at 12 months was observed in 68.9% of the 30%-dose group and 92.9% of the half-dose group (p=0.001). Visual acuity (a secondary outcome measure) improved from 20/32 to 20/20 in both groups, with a mean between-group difference of 1.7 letters. In the 30%-dose group, 4 (6.6%) eyes lost 5 or more letters compared with 0 eyes in the half-dose group. This study did not provide sufficient evidence of a functional benefit that would outweigh the potential risk of treatment with verteporfin photodynamic therapy for acute central serous chorioretinopathy.

Salehi et al (2015), in their network meta-analysis which included a total of 25 studies (total N=1098 patients; 1098 eyes), judged these studies to be at low risk of bias in most domains with the exception of attrition bias (6% of the 30% verteporfin photodynamic therapy group vs 13% of the 50% verteporfin photodynamic therapy group) and selective outcomes reporting (primary and secondary outcomes were designated differently on the trial registry entry and the published report). The 30% dose did not achieve noninferiority.

**Section Summary: Acute Central Serous Chorioretinopathy**

The evidence for the efficacy of verteporfin photodynamic therapy for acute central serous chorioretinopathy includes 2 RCTs. This evidence, although demonstrating that full- and reduced-dose verteporfin photodynamic therapy results in small improvements in best-corrected visual acuity, did not meet the clinically meaningful threshold. Comparative and adequately powered trials are needed to evaluate the efficacy of verteporfin photodynamic therapy in acute central serous chorioretinopathy.

**Chronic Central Serous Chorioretinopathy**

Reductions in subretinal fluid and improvement in retinal anatomy, visual acuity, and retinal sensitivity have been observed in 70% to 100% of cases in multiple retrospective studies. Use of reduced dose verteporfin photodynamic therapy for chronic central serous chorioretinopathy also has been reported. Uetani et al (2012) compared half-dose with one-third dose verteporfin photodynamic therapy in a small (N=16 eyes) prospective open-label trial. At 3 months, all 10 (100%) eyes in the half-dose verteporfin photodynamic therapy group and 2 (33%) eyes in the one-third-dose verteporfin photodynamic therapy group had complete resolution of subretinal fluid. Patients in the half-dose verteporfin photodynamic therapy group gained an average of 5.4 letters while patients in the one-third-dose group gained 1.7 letters (p=NS). Chan et al (2008) also reported on reduced-dose verteporfin for the treatment of chronic central serous chorioretinopathy in a prospective series of 48 patients. Mean duration of central serous chorioretinopathy was 8.2 months (range, 3-40 months). At 12 months after verteporfin photodynamic therapy, mean best-corrected visual acuity improved from 0.31 to 0.15 logarithm of the minimum angle of resolution, an improvement of 1.6 lines.
**Section Summary: Chronic Central Serous Chorioretinopathy**

The evidence for the efficacy of verteporfin photodynamic therapy for chronic central serous chorioretinopathy includes multiple retrospective studies. Although this relatively large body of studies has indicated that half-dose verteporfin photodynamic therapy yields positive functional and anatomic outcomes while, at the same time, reducing the potential adverse events associated with conventional verteporfin photodynamic therapy, no comparative data have shown the relative efficacy of multiple verteporfin photodynamic therapy strategies. Comparative trials are needed to evaluate the efficacy of verteporfin photodynamic therapy strategies in chronic central serous chorioretinopathy.

**Polypoidal Choroidal Vasculopathy**

**Verteporfin Photodynamic Therapy**

A systematic review by Chan et al (2010) included 30 studies assessing verteporfin photodynamic therapy in patients with polypoidal choroidal vasculopathy. Reviewers found numerous case series reporting favorable anatomic outcomes and visual acuity for patients treated with verteporfin photodynamic therapy. Some of these studies are described below. Tang et al (2015) also published a systematic review and meta-analysis evaluating treatment for polypoidal choroidal vasculopathy. Two RCTs compared verteporfin photodynamic therapy with ranibizumab and reported a weighted mean difference in visual acuity of 0.06 logarithm of the minimum angle of resolution (95% CI, -0.01 to 0.12 logarithm of the minimum angle of resolution) in favor of ranibizumab, but this difference was not statistically significant.

Several nonrandomized studies from Asia have been reported. Hikichi et al (2011) reported on the largest prospective consecutive series of 220 eyes of 210 Japanese patients with polypoidal choroidal vasculopathy who were followed for 1 year after the primary verteporfin photodynamic therapy. A single physician, diagnosed, treated and followed all patients (not masked). Retreatment was considered every 3 months based on the examination findings, and there was an average of 1.37 treatments. Fluid, exudates, and hemorrhages had resolved in 205 (93%) eyes at 1-year follow-up. Average visual acuity improved by more than 0.3 logarithm of the minimum angle of resolution in 55 (25%) of eyes, remained stable in 143 (65%) of eyes, and decreased more than 0.3 logarithm of the minimum angle of resolution in 21 (10%) of eyes.

Akaza et al (2011) reported on 3-year follow-up of 43 eyes (43 patients) treated with verteporfin photodynamic therapy for polypoidal choroidal vasculopathy. Before the initial verteporfin photodynamic therapy, 40 (93%) eyes exhibited polypoidal choroidal vasculopathy in the narrow sense and 3 (7%) exhibited polypoidal choroidal neovascularization. Number of treatment sessions during follow-up ranged from 1 to 8. At 3-year follow-up, mean visual acuity decreased to below baseline. Polypoidal lesions recurred in 33 (77%) of the 43 eyes at 3 years, although the 3 eyes with polypoidal choroidal neovascularization showed little change except for enlargement and recurrence. Long-term visual outcomes following verteporfin photodynamic therapy showed a high frequency of recurrent polypoidal lesions as well as enlargement and neovascular changes of abnormal vascular networks. However, because polypoidal lesions recurred after verteporfin photodynamic therapy in some cases, further study is needed to confirm the long-term effectiveness of verteporfin photodynamic therapy for polypoidal choroidal vasculopathy.
Section Summary: Verteporfin Photodynamic Therapy for Polypoidal Choroidal Vasculopathy

Available evidence on the efficacy of verteporfin photodynamic therapy for polypoidal choroidal vasculopathy consists of several retrospective studies and a meta-analysis that included 2 RCTs. Retrospective studies have reported favorable anatomic outcomes and visual acuity for patients treated with verteporfin photodynamic therapy. RCTs comparing verteporfin photodynamic therapy with antivascular endothelial growth therapies have reported no statistical differences in visual acuity. Controlled trials are needed to permit conclusions on the efficacy of verteporfin photodynamic therapy monotherapy in polypoidal choroidal vasculopathy.

Verteporfin Photodynamic Therapy Plus Anti-Vascular Endothelial Growth Factor Therapy

Tang et al (2015) published a systematic review that evaluated treatment for polypoidal choroidal vasculopathy. A single RCT, which compared verteporfin photodynamic therapy with verteporfin photodynamic therapy plus ranibizumab, reported a nonsignificant weighted mean difference of -0.08 logarithm of the minimum angle of resolution (95% CI, -0.20 to 0.04 logarithm of the minimum angle of resolution) in favor of combination therapy.

Lim et al (2012) randomized 31 patients with age-related macular degeneration and 10 patients with polypoidal choroidal vasculopathy to bevacizumab alone or bevacizumab plus verteporfin photodynamic therapy. Bevacizumab was administered at 6-week intervals for the first 18 weeks, and then at 3-month intervals, as needed. At 12 months, the monotherapy and combined treatment groups showed similar improvements in best-corrected visual acuity and central foveal thickness. Patients with polypoidal choroidal vasculopathy did not show significant improvements in best-corrected visual acuity (p=0.050) or central foveal thickness (p=0.088) when analyzed alone; however, the trial was likely underpowered for this subgroup analysis.

EVEREST (Efficacy and Safety of Verteporfin Added to Ranibizumab in the Treatment of Symptomatic Macular Polypoidal Choroidal Vasculopathy, 2012) was a small, exploratory, multicenter, double-masked, randomized trial of verteporfin photodynamic therapy, ranibizumab, or verteporfin photodynamic therapy plus ranibizumab in 61 treatment-naive Asian patients with polypoidal choroidal vasculopathy. Patients in the verteporfin photodynamic therapy-only group (angio-occlusive) received sham ranibizumab, and patients in the ranibizumab monotherapy group (angiogenic and antipermeability) received sham verteporfin photodynamic therapy. The primary end point (the proportion of patients with complete regression of polyps at 6 months) showed verteporfin photodynamic therapy alone (71.4%) or in combination with ranibizumab (77.8%) to be superior to ranibizumab monotherapy (28.6%) in achieving complete polyp regression. Mean improvement in best-corrected visual acuity was generally similar for the 3 groups (7.5 letters for verteporfin photodynamic therapy, 10.9 letters for combined treatment, 9.2 letters for ranibizumab alone). The proportion of patients gaining at least 15 letters was 19% in the verteporfin photodynamic therapy group, 21% in the combination group, and 33% in the ranibizumab monotherapy group. Interpretation of the visual acuity results is limited because the trial was not powered to assess differences in best-corrected visual acuity. There were no new safety findings.

Observational studies have also been published. Kang et al (2013) reported on 5-year retrospective follow-up for 42 eyes (36 patients) treated with verteporfin photodynamic therapy for polypoidal choroidal vasculopathy. Patients received a mean of 2.21 verteporfin photodynamic therapy
treatments during the study, with additional intravitreal injections of antivascular endothelial growth agents if exudative changes were observed. During follow-up, recurrence was observed in 33 (78.6%) eyes, and the mean number of antivascular endothelial growth injections was 6.42 in eyes with recurrence. In the entire group, best-corrected visual acuity improved from 0.78 logarithm of the minimum angle of resolution at baseline (20/120 Snellen equivalent) to 0.67 logarithm of the minimum angle of resolution (20/93 Snellen equivalent) at 5 years. Using a change of at least 0.3 logarithm of the minimum angle of resolution as a threshold, best-corrected visual acuity improved in 14 (33.3%) eyes, remained stable in 23 (54.8%) eyes, and decreased in 5 (11.9%) eyes. Interpretation of this study is difficult because all patients received combination treatment with intravitreal vascular endothelial growth factor antagonists without comparison groups. Kim and Yu (2011) retrospectively reviewed 39 consecutive patients with polypoidal choroidal vasculopathy who received verteporfin photodynamic therapy (before April 2007) or combination verteporfin photodynamic therapy plus intravitreal bevacizumab (after April 2007). During 12 months of follow-up, patients in the monotherapy group (n=19) received a mean of 1.89 verteporfin photodynamic therapy applications, and patients in the combined therapy group (n=20) received a mean of 1.30 verteporfin photodynamic therapy applications and 2.90 bevacizumab injections. Best-corrected visual acuity improved by 3.0 lines in the combined therapy group compared with 1.6 lines in the verteporfin photodynamic therapy-only group. This level of improvement in best-corrected visual acuity was achieved in 55.0% in the combined therapy group and 36.8% in the monotherapy group.

Section Summary: Verteporfin Photodynamic Therapy Plus Anti-Vascular Endothelial Growth Factor Therapy for Polypoidal Choroidal Vasculopathy

Available evidence on the efficacy of verteporfin photodynamic therapy for polypoidal choroidal vasculopathy consists of 2 small RCTs, a meta-analysis, and 2 retrospective studies. While results of 1 RCT reported no difference in visual acuity for patients treated with verteporfin photodynamic therapy plus antivascular endothelial growth therapy vs verteporfin photodynamic therapy alone, the other trial reported improvement in visual acuity, but the effect was not statistically significant. Adequately powered controlled trials are needed to permit conclusions on the efficacy of combination verteporfin photodynamic therapy plus antivascular endothelial growth therapy in polypoidal choroidal vasculopathy.

Choroidal Hemangioma

The systematic review by Chan (2010) included 11 case series on verteporfin photodynamic therapy in patients with choroidal hemangioma. Verteporfin photodynamic therapy has been reported to induce complete and irreversible occlusion of the microvasculature, although this may require more than 1 treatment. Several case series have demonstrated encouraging visual acuity and anatomic outcomes in 150 patients with circumscribed choroidal hemangioma treated with various verteporfin photodynamic therapy regimens.

Blasi et al (2010) reported on 5-year outcomes for a prospective series of 25 consecutive patients with symptomatic choroidal hemangioma. Twenty-two (88%) patients received a single verteporfin photodynamic therapy session and 3 eyes received a second verteporfin photodynamic therapy session. Follow-up examinations were performed 2 weeks, 1 month, 3 months, and every 6 months after treatment. All tumors were reduced in size, and there were no recurrences through 5 years of follow-up. At 1 year, best-corrected visual acuity improved by an average of 18.2 letters. Visual acuity improved by
2 or more lines in 20 (80%) eyes and by 3 or more lines in 12 (48%) eyes. No treated eyes lost visual acuity between the 1- and 5-year follow-ups. Foveal center thickness decreased from a mean of 386.20 μm to 179.2 μm at 5 years, and there was the resolution of macular exudation in all cases. No treatment-related adverse events were identified.

**Section Summary: Choroidal Hemangioma**

Available evidence on the efficacy of verteporfin photodynamic therapy for choroidal hemangioma consists of a systematic review of 11 case series and a prospective study. This body of evidence has suggested a favorable effect of verteporfin photodynamic therapy on various visual acuity and anatomic outcomes in patients with a choroidal hemangioma. Controlled trials with a larger number of patients and longer follow-up are needed to permit conclusions regarding the efficacy of verteporfin photodynamic therapy for this indication.

**Angioid Streaks**

The systematic review by Chan (2010) included 8 case series on verteporfin photodynamic therapy assessing 148 patients with angioid streaks. Reviewers concluded that verteporfin photodynamic therapy might limit or slow vision loss compared with the expected natural course of choroidal neovascularization due to angioid streaks, but 1 study showed a decrease in visual acuity following verteporfin photodynamic therapy, and others showed that substantial proportions of patients continued to lose visual acuity. Thus, further studies are warranted to assess long-term safety and efficacy of verteporfin photodynamic therapy in these patients.

**Section Summary: Angioid Streaks**

Available evidence on the efficacy of verteporfin photodynamic therapy for angioid streaks consists of a systematic review of case series. The data from case series have reported conflicting results for visual acuity. Controlled trials with a larger number of patients and longer follow-up are needed to permit conclusions on the efficacy of verteporfin photodynamic therapy in angioid streaks, especially if it is effective in limiting the growth of choroidal neovascularization.

**Inflammatory Chorioretinal Conditions**

choroidal neovascularization can occur as a complication of inflammatory conditions such as uveitis, multifocal choroiditis and panuveitis, and punctate inner choroidopathy. About one-third of patients develop choroidal neovascularization, which can result in severe vision loss if it is subfoveal.

The systematic review by Chan (2010) included 15 case reports evaluating verteporfin photodynamic therapy in 115 patients with inflammatory eye conditions. Encouraging visual acuity, and anatomic improvements have been reported with verteporfin photodynamic therapy for punctuate inner choroidopathy, choroiditis and toxoplasmic retinochoroiditis, and subfoveal choroidal neovascularization secondary to posterior uveitis. While promising, larger and comparative studies are needed to evaluate the effect of verteporfin photodynamic therapy on health outcomes for this indication.
Section Summary: Inflammatory Chorioretinal Conditions

Available evidence on the efficacy of verteporfin photodynamic therapy for inflammatory chorioretinal conditions consists of multiple case reports. Controlled trials are needed to permit conclusions on the efficacy of verteporfin photodynamic therapy in ocular inflammatory conditions.

Summary of Evidence

Age-Related Macular Degeneration

For individuals who have classic choroidal neovascularization due to age-related macular degeneration who receive verteporfin photodynamic therapy, the evidence includes randomized controlled trials (RCTs) and systematic reviews of controlled trials. Relevant outcomes are symptoms, change in disease status, functional outcomes, and quality of life. Multiple RCTs have supported the superiority of verteporfin photodynamic therapy in reducing vision loss and decreasing retinal thickness compared with placebo or sham procedure. The evidence is sufficient to determine that the technology results in a meaningful improvement in the net health outcome.

For individuals who have choroidal neovascularization due to age-related macular degeneration who receive verteporfin photodynamic therapy plus antivascular endothelial growth factor therapy, the evidence includes 2 confirmatory RCTs (and their multiple analyses), multiple smaller RCTs, and a meta-analysis of existing trials. Relevant outcomes are symptoms, change in disease status, functional outcomes, and quality of life. This evidence does not demonstrate improvements in visual acuity using combination therapy compared with antivascular endothelial growth factor monotherapy. Combination therapy may reduce the number of intravitreal injections needed, but this result has not been consistently reported across studies. The evidence is insufficient to determine the effects of the technology on health outcomes.

For individuals who have choroidal neovascularization due to age-related macular degeneration who receive verteporfin photodynamic therapy plus corticosteroids and/or antivascular endothelial growth factor therapy, the evidence includes 3 small RCTs. Relevant outcomes are symptoms, change in disease status, functional outcomes, and quality of life. The evidence does not demonstrate improvements in visual acuity with combination therapy. The evidence is insufficient to determine the effects of the technology on health outcomes.

Pathologic Myopia

For individuals who have choroidal neovascularization due to pathologic myopia who receive verteporfin photodynamic therapy, the evidence includes a subgroup analysis from a large RCT. Relevant outcome are symptoms, change in disease status, functional outcomes, and quality of life. The subgroup analysis showed verteporfin photodynamic therapy was more effective than placebo in preventing vision loss at one year but not in the second year. The evidence is sufficient to determine that the technology results in a meaningful improvement in the net health outcome.

For individuals who have choroidal neovascularization due to pathologic myopia who receive verteporfin photodynamic therapy plus antivascular endothelial growth factor therapy, the evidence includes a small RCT and a retrospective cohort study. Relevant outcomes are symptoms, change in disease status, functional outcomes, and quality of life. The single RCT was likely underpowered to detect a clinically
meaningful change in visual acuity outcomes. The retrospective cohort study did not demonstrate improvements in visual acuity with combination treatment. The evidence is insufficient to determine the effects of the technology on health outcomes.

**Presumed Ocular Histoplasmosis**

For individuals who have choroidal neovascularization due to presumed ocular histoplasmosis who receive verteporfin photodynamic therapy, the evidence includes a small RCT and a prospective cohort study. Relevant outcomes are symptoms, change in disease status, functional outcomes, and quality of life. Lack of a control arm in the prospective cohort study and 50% lost to follow-up in the RCT preclude a meaningful interpretation of data of observed improvements in visual acuity outcomes. The evidence is insufficient to determine the effects of the technology on health outcomes.

**Central Serous Chorioretinopathy**

For individuals who have choroidal neovascularization due to acute central serous chorioretinopathy who receive verteporfin photodynamic therapy, the evidence includes 2 RCTs. Relevant outcomes are symptoms, change in disease status, functional outcomes, and quality of life. Although the evidence has demonstrated that full and reduced doses of verteporfin photodynamic therapy result in a small improvement in visual acuity outcomes, the improvements did not meet clinically meaningful thresholds. The evidence is insufficient to determine the effects of the technology on health outcomes.

For individuals who have choroidal neovascularization due to chronic central serous chorioretinopathy who receive verteporfin photodynamic therapy, the evidence includes multiple retrospective studies. Relevant outcomes are symptoms, change in disease status, functional outcomes, and quality of life. Although this relatively large body of retrospective studies has shown that half-dose verteporfin photodynamic therapy yields positive functional and anatomic outcomes while, at the same time, reducing the potential adverse events associated with conventional verteporfin photodynamic therapy, data from RCTs for multiple verteporfin photodynamic therapy strategies are lacking. The evidence is insufficient to determine the effects of the technology on health outcomes.

Clinical input obtained in 2012 supported the use of verteporfin photodynamic therapy for chronic central serous chorioretinopathy, and therefore verteporfin photodynamic therapy may be considered medically necessary for this indication.

**Polypoidal Choroidal Vasculopathy**

For individuals who have choroidal neovascularization due to polypoidal choroidal vasculopathy who receive verteporfin photodynamic therapy, the evidence includes several prospective cohort studies and a meta-analysis of 2 RCTs. Relevant outcomes are symptoms, change in disease status, functional outcomes, and quality of life. Prospective cohort studies have reported favorable anatomic and visual acuity outcomes for patients treated with verteporfin photodynamic therapy. However, RCTs comparing verteporfin photodynamic therapy with antivascular endothelial growth factor therapies have reported no statistically significant differences in visual acuity outcomes. The evidence is insufficient to determine the effects of the technology on health outcomes.
For individuals who have choroidal neovascularization due to polypoidal choroidal vasculopathy who receive verteporfin photodynamic therapy plus antivascular endothelial growth factor therapy, the evidence includes 2 small RCTs, a meta-analysis, and 2 retrospective cohort studies. Relevant outcomes are symptoms, change in disease status, functional outcomes, and quality of life. Results of the 2 RCTs failed to demonstrate statistically significant differences in visual acuity outcomes. The evidence is insufficient to determine the effects of the technology on health outcomes.

**Choroidal Hemangioma**

For individuals who have choroidal neovascularization due to choroidal hemangioma who receive verteporfin photodynamic therapy, the evidence includes a systematic review of case series and a prospective cohort study. Relevant outcomes are symptoms, change in disease status, functional outcomes, and quality of life. Although the prospective cohort suggested a favorable effect of verteporfin photodynamic therapy on various visual acuity and anatomic outcomes in patients with choroidal hemangioma, data from RCTs are lacking. The evidence is insufficient to determine the effects of the technology on health outcomes.

**Angioid Streaks**

For individuals who have choroidal neovascularization due to angioid streaks who receive verteporfin photodynamic therapy, the evidence includes a systematic review of case series. Relevant outcomes are symptoms, change in disease status, functional outcomes, and quality of life. Data from multiple case series have shown conflicting results for visual acuity outcomes. The evidence is insufficient to determine the effects of the technology on health outcomes.

**Inflammatory Chorioretinal Conditions**

For individuals who have choroidal neovascularization due to inflammatory chorioretinal conditions who receive verteporfin photodynamic therapy, the evidence includes a systematic review of case reports. Relevant outcomes are symptoms, change in disease status, functional outcomes, and quality of life. Methodologic limitations limit the conclusions drawn from 15 case reports (total N=115 patients) of multiple disease indications. The evidence is insufficient to determine the effects of the technology on health outcomes.

**SUPPLEMENTAL INFORMATION**

**Clinical Input from Physician Specialty Societies and Academic Medical Centers**

While the various physician specialty societies and academic medical centers may collaborate with and make recommendations during this process, through the provision of appropriate reviewers, input received does not represent an endorsement or position statement by the physician specialty societies or academic medical centers, unless otherwise noted.

In response to requests, input was received from 2 physician specialty societies and 2 academic medical centers while this policy was under review in 2012. Input agreed that photodynamic therapy alone is medically necessary for age-related macular degeneration, pathological myopia, presumed ocular histoplasmosis, central serous chorioretinopathy, and choroidal hemangioma. Input was mixed on the
use of photodynamic therapy for other ophthalmologic disorders. Input agreed that photodynamic therapy used in combination with vascular endothelial growth factor antagonists is investigational for all ophthalmologic disorders.

**Practice Guidelines and Position Statements**

**American Academy of Ophthalmology**

A 2015 preferred practice pattern guideline on age-related macular degeneration from the American Academy of Ophthalmology has described verteporfin photodynamic therapy as a treatment option approved by the U.S. Food and Drug Administration for subfoveal lesions and predominantly classic choroidal neovascularization (choroidal neovascularization) related to age-related macular degeneration.63.

The 2015 update stated that antivascular endothelial growth factor therapies have become first-line therapy for treating and stabilizing most cases of age-related macular degeneration. Verteporfin photodynamic therapy is a less commonly used treatment for neovascular age-related macular degeneration; recommendations stated that the following diagnoses are eligible for verteporfin photodynamic therapy:

- “Macular choroidal neovascularization, new or recurrent, where the classic component is >50% of the lesion and the entire lesion is ≤5400 µm in greatest linear diameter
- Occult choroidal neovascularization may be considered for PDT [photodynamic therapy] with vision <20/50 or if the choroidal neovascularization is <4 MPS [macular photocoagulation study] disc areas in size when the vision is >20/50
- Juxtafoveal choroidal neovascularization is an off-label indication for PDT but may be considered in select cases.”

**National Institute for Health and Care Excellence**

In 2018, the National Institute for Health and Care Excellence updated its 2003 guidance on the use of photodynamic therapy for age-related macular degeneration.64,65 The Institute made the following recommendations: it recommended against use of photodynamic therapy as monotherapy for late (wet) age-related macular degeneration and against use of photodynamic therapy as first-line adjunctive therapy to antivascular endothelial growth factor therapies for late (wet) age-related macular degeneration; it recommended for photodynamic therapy as second-line adjunctive therapy to antivascular endothelial growth factor therapies for late (wet) age-related macular degeneration in a trial setting.

**Canadian Agency for Drugs and Technologies in Health**

In 2008, the Canadian Agency for Drugs and Technologies in Health released a health technology assessment on the management of neovascular age-related macular degeneration.66 The Agency concluded that “Overall, the efficacy of antivascular endothelial growth therapies over V-photodynamic therapy is well supported by RCTs [randomized controlled trials]. What remains unclear is whether combination therapy (and which combinations) are superior or merely equal to monotherapy.”
U.S. Preventive Services Task Force Recommendations

Not applicable.

Medicare National Coverage

Since 2001, use of ocular photodynamic therapy has been covered by Medicare for the treatment predominantly classical subfoveal choroidal neovascularization (ie, occupies ≥50% of the area of the entire lesion) associated with age-related macular degeneration only when used in conjunction with verteporfin. However, there was no national Medicare coverage policy for other indications. In 2004, Medicare found evidence to conclude that photodynamic therapy with verteporfin may be “reasonable and necessary” for patients with age-related macular degeneration with “subfoveal occult or minimally classic choroidal neovascularization ... 4 disk areas or less in size ... [with] evidence of progression within the three months prior to initial treatment.” Medicare also reiterated that use of ocular photodynamic therapy with verteporfin for indications such as “pathologic myopia or the presumed histoplasmosis syndrome” may be “eligible for coverage through individual contractor discretion.”

Ongoing and Unpublished Clinical Trials

Some currently ongoing trials that might influence this review are listed in Table 1.

Table 1. Summary of Key Trials

<table>
<thead>
<tr>
<th>NCT No.</th>
<th>Trial Name</th>
<th>Planned Enrollment</th>
<th>Completion Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>NCT01797861</td>
<td>Prospective Randomized Controlled Treatment Trial for Chronic Central Serous Chorioretinopathy (PLACE)</td>
<td>140</td>
<td>May 2017 (completed; no results posted)</td>
</tr>
<tr>
<td>NCT02495181</td>
<td>Randomized, Double-masked, Sham-controlled Phase 4 Study, Efficacy, Safety, and Tolerability of Intravitreal Aflibercept Monotherapy Compared to Aflibercept With Adjunctive Photodynamic Therapy in Patients with Polypoidal Choroidal Vasculopathy (ATLANTIC)</td>
<td>50</td>
<td>Dec 2019 (completed; no results posted)</td>
</tr>
<tr>
<td>NCT02821520</td>
<td>Initial Versus Delayed PDT Combination with Conbercept in Polypoidal Choroidal Vasculopathy</td>
<td>80</td>
<td>Jun 2019</td>
</tr>

</table>

NCT: national clinical trial; PDT: photodynamic therapy.
* Denotes industry-sponsored or co-sponsored trial.

ESSENTIAL HEALTH BENEFITS

The Affordable Care Act (ACA) requires fully insured non-grandfathered individual and small group benefit plans to provide coverage for ten categories of Essential Health Benefits (“EHBs”), whether the benefit plans are offered through an Exchange or not. States can define EHBs for their respective state.

States vary on how they define the term small group. In Idaho, a small group employer is defined as an employer with at least two but no more than fifty eligible employees on the first day of the plan or
contract year, the majority of whom are employed in Idaho. Large group employers, whether they are self-funded or fully insured, are not required to offer EHBs, but may voluntarily offer them.

The Affordable Care Act requires any benefit plan offering EHBs to remove all dollar limits for EHBs.

**CODES**

<table>
<thead>
<tr>
<th>Codes</th>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPT</td>
<td>67221</td>
<td>Destruction of localized lesions of choroid (eg, choroidal neovascularization); photodynamic therapy (includes intravenous infusion)</td>
</tr>
<tr>
<td></td>
<td>67225</td>
<td>; photodynamic therapy, second eye, at single session (list separately in addition to code for primary eye treatment)</td>
</tr>
<tr>
<td>HCPCS</td>
<td>J3396</td>
<td>Injection, verteporfin, 0.1 mg</td>
</tr>
</tbody>
</table>

Verteporfin Photodynamic Therapy is considered investigational when used in combination with the drugs below:

- C9257 Injection, bevacizumab, 0.25 mg
- J0178 Injection, aflibercept, 1 mg
- J2503 Injection, pegaptanib sodium, 0.3 mg
- J2778 Injection, ranibizumab, 0.1 mg

**ICD-10-CM**

- B39.9 Histoplasmosis, unspecified
- D18.09 Hemangioma of other sites
- H32 Chorioretinal disorders in diseases classified elsewhere
- H35.30 Unspecified macular degeneration
- H35.3110-H35.3194 Nonexudative age-related macular degeneration code range
- H35.3210-H35.3293 Exudative age-related macular degeneration code range
- H35.711-H35.719 Central serous chorioretinopathy, code range
- H44.20-H44.23 Degenerative myopia code range

**ICD-10-PCS**

ICD-10-PCS codes are only used for inpatient services. There is no specific ICD-10-PCS code for this procedure.

**Type of Service** Vision

**Place of Service** Physician’s Office
### POLICY HISTORY

<table>
<thead>
<tr>
<th>Date</th>
<th>Action</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>06/12/14</td>
<td>Replace policy</td>
<td>Policy updated with literature review through May 28, 2014; some references removed; policy statements unchanged</td>
</tr>
<tr>
